"The terminology of this group is likely to become confusing if, at present, we identify with each other the fowl typhoid and the pullorum types. A better plan would be to adhere, for the time being, to the separation, until a much larger number of races have been carefully studied, and fluctuating and permanent differences recorded. If these organisms should prove to be a species in the making which has not yet acquired its final characters, other variations than those to which we have referred may be encountered."

Influence of sickness of cattle on the milk, F. Zaribnicky (Arch. Wiss. u. Prakt. Tierheilk., 40 (1914), No. 4-5, pp. 355-381).—In this study it was found that the fat content is quite variable in disease, in some cases there being a rapid rise in fat content and in others a reduction, ranging from 1.7 per cent with cows affected with mastitis (E. S. R., 27, p. 878) to 19.5 per cent with

those affected with foot-and-mouth disease. There were some variations in the milk sugar content but not so great as in the fat, the majority of cases ranging from 4.5 to 5.5 per cent with several cases as low as 1. In ash content there was as a rule little variation from the normal. Except in cases of abnormally high or low fat content, the specific gravity of the milk varied but little from the normal. The casein content appeared to be lower than the normal except in cases of mastitis and foot-and-mouth disease. Among the diseases studied were mastitis, foot-and-mouth disease, intestinal catarrh, endometritis, pyelonephritis, and diseases of the respiratory organs.

Some drugs recently used in veterinary practice, J. N. Frost (Cornell Vet., 4 (1915), No. 4, pp. 190–193).—The author states that during the year four herds in which infectious mastitis was spreading rapidly were treated with methylene blue. Each cow was given 60 grains, followed by a dose of 30 grains the following night and morning. In all cases treated the dose was sufficient to cause the milk to be colored. Rapid recoveries followed in all the herds without the loss of a single quarter or the production of a hard milker. It is stated that one of these herds had been troubled nearly every year by infectious mastitis with the loss of the udder or a section of it and the production of hard milkers by the formation of fibrous growths, commonly called spider in the teat canal.

Kidney worm infestation of swine in the Philippine Islands with special reference to the pathological changes, W. H. BOYNTON (Philippine Jour. Sci., Sect. B, 9 (1914), No. 3, pp. 269-289, pls. 3).—This report of studies of the pathological changes induced by the kidney worm (Stephanurus deutatus) is based upon the examination of pigs imported into the Philippines.

Infestation with *S. dentatus* is characterized by muscular pains, tenderness to pressure over the kidneys, weakness, loss of appetite, emaciation, and partial or complete paralysis of the hind quarters. "The parasites may be located in the fat surrounding the kidneys, in the ureters, and encysted in the kidneys, liver, spleen, lymph glands, and muscles and connective tissues in the region of the kidneys; also, they may be found free, slightly embedded, or encysted in the connective tissue of both peritoneal and thoracic cavities."

The age at which pigs usually die from infestation with *S. dentatus* and the lesions produced by this parasite indicate a slow-developing chronic disease. "Since the average age of pigs that are killed for meat at the Manila matadero varies from six months to one and one-half years, the disease does not have time to cause any fatal or very damaging lesions in the animals. Hence it is not looked upon as very serious in connection with meat inspection. In older animals the lesions are more serious.

"From the several autopsies made on animals, it is concluded that kidney worm infestation becomes a generalized instead of a localized disease of swine when allowed to run its course. Practically every cavity of the body may become infested."

Attention is called to the fact that observations reported by Newcomb (E. S. R., 30, p. 384) show the infestation to be prevalent in native hogs slaughtered at Manila.

Hog cholera or Pintadilla, B. M. Bolton (Estac. Expt. Agron. Cuba Circ. 46 (1914), pp. 16, fig. 1).—A general account of the nature of this disease, symptoms, duration, etc., vaccination, the disposition of animals that die of the disease, and the advisability of disinfecting the premises where it has existed.

Hog cholera questions and answers, F. B. Hadley (Wisconsin Sta. Circ. 54 (1914), pp. 3-28. figs. 10).—This circular deals with the nature and occurrence of hog cholera in Wisconsin, its cause, diagnosis, prevention and control, and

treatment, including the use of hog cholera serum and virus and the results that have been obtained in Wisconsin.

Hog cholera and its prevention by the use of antihog-cholera serum, B. B. Flowe (Bul, N. C. Dept, Agr., 35 (1914), No. 7, pp. 29, figs. 15),—An account of hog cholera, its nature, prevention and methods of eradication. The manufacture of antihog-cholera serum is described and the bulletin is well illustrated.

Basis of the serum treatment for hog cholera, C. F. Lyncu (Amer. John. Vet. Med., 9 (1914), Nos. 7, pp. 473–480; 8, pp. 580–583).—A brief survey of the principles underlying immunity and an account of the use of the serum and serum virus methods of treating hog cholera.

Environment as a factor in complications following vaccination for the prevention of hog cholera, S. Sheldon (Amer. Jour. Vet. Med., 9 (1914), No. 7, pp. 489, 490).—"After a herd has been properly vaccinated, it should be placed in a paddock or pasture where mudholes and stagnant pools are absent. . . . We feel that this is a very important matter and should be insisted upon at all times."

Conditions in which antihog-cholera serum should not be used, O. E. Troy (Amer. Jour. Vet. Med., 9 (1914), No. 7, pp. 480, 481).—The tenor of this paper is that a diagnosis of hog cholera must be positively made before serum or similar treatment is employed. The serum virus method should only be used under the proper auspices.

"Unless there is immediate danger of infection, pregnant sows should not be immunized, particularly with the simultaneous method, as the immunizing process may produce abortion. Careful handling and the use of serum alone minimizes this danger. Swine that are to be introduced to noninfected premises where there are noninfected, susceptible hogs, should not be given the simultaneous treatment within 30 days of their introduction, because such immunized hogs may be virus earriers. Herds to which any new stock is being added should, as a rule, be protected unless careful quarantine of the new stock is observed. Serum alone has proved impractical on infected farms where conditions do not permit of thorough cleaning and disinfection, and in feed lots where new hogs are periodically added."

Some failures for which serum has been wrongly blamed, C. H. Bugber (Amer. Jour. Vet. Med., 9 (1914), No. 7, pp. 484-486).—Increased caution in operation and in administering hog-cholera serum is deemed necessary. Laxity in this regard accounts for much of the failures in the use of antihog-cholera serum.

The proper time to vaccinate hogs, R. A. Branson (Amer. Jour. Vet. Med., 9 (1914), No. 9, pp. 651, 652).—After giving his experiences in immunizing swine, the author concludes that "the proper time to vaccinate is when the pig is from six to eight weeks of age."

Care of the herd after vaccination, D. S. BURCHAM (Amer. Jour, Vet. Med., 9 (1914), No. 7, pp. 483, 484).—A discussion with recommendations.

Spreading disease among coyotes, M. A. Cromwell (Breeder's Gaz., 67 (1915), No. 3, pp. 110, 111).—It is stated that the inoculation of young coyotes with sarcoptic mange mites and turning them loose at Great Falls. Mont., to infect other wild coyotes has succeeded in spreading the disease. The coyotes of that locality are said to be dying by the hundreds and in fact becoming nearly extinct in some places. The author reports that sheepmen at a recent meeting favored the removal of the bounty from coyotes, especially those that are infected with mange, and of putting more efforts and money into the disease work.

Tuberculosis in poultry, C. H. Higgins (Canada Expt. Farms Rpts. 1913, pp. 687-689).—A brief popular account.

Blackhead in turkeys (enterohepatitis), C. II. Higgins (Canada Expt. Farms Rpts. 1913, pp. 683-686).—An account of this disease and its prevention and treatment.

Lice and mites: Life history and extermination, Helen D. WHITAKER (Washington Sta. Popular But. 74 (1914), pp. 7).—A popular account of the ectoparasites of poultry and means for their control.

RURAL ENGINEERING.

River and canal engineering, E. S. Bellasis (London and New York, 1913, pp. X+215, figs. 72).—It is the object of this book to describe the characteristics of open-flowing streams and the principles and methods to be followed in dealing with them. The subject matter is presented under the following chapters: Rainfall, collection of information concerning streams, the silting and scouring action of streams, methods of increasing or reducing silting or scour, works for the protection of banks, diversions and closures of streams, the training and canalization of rivers, canals and conduits, weirs and sluices, bridges and syphons, drainage and floods, reservoirs and dams, tidal waters and works, and river bars.

Report of investigations of land settlement and irrigation development in America, E. Mead (Methourne, Aust., 1914, pp. 10).—This is a general report on the subject.

An economic phase of irrigation, A. M. PAUL (West, Engin., 5 (1914), No. 4, pp. 163, 164).—The author discusses the application of the law of minimum to the use of irrigation water.

Notes on irrigation and cooperative irrigation societies in Ilocos Norte, E. B. Christie (*Philippine Jour. Sci., Sect. D, 9 (1914*), No. 2, pp. 99-113, pl. 1).—It is the object of this article to convey a general idea of the degree of development of native irrigation in Ilocos Norte and to give a detailed description of the irrigation works in Bacarra and Bintar.

Irrigation and canal building in British India, E. JACQUEREZ (Min. Agr. [France], Ann. Forets, Hydraul. [ctc.], No. 43 (1912), pp. 337-421, pls. 5, figs. 23).—The author discusses in some detail the phases of irrigation as practiced in British India, taking up particularly methods of elevating irrigation water, irrigation canals, design and alignment of permanent canals, chutes, rapids and flumes, dams and water storage, water measurement and distribution, and administration and cost of irrigation enterprises and the resulting revenues. Discussions of the design of irrigation structures involving mathematical calculations are given and typical structures are illustrated.

Concrete lining, Franklin Canal, Rio Grande project, L. M. Lawson (Engiu. News, 72 (1914), No. 11, pp. 549-543, figs. 8).—The construction of the concrete lining necessary to increase the canal capacity is described and illustrated. A 4-in, thickness of concrete was placed with forms on a 1½:1 slope. Cost data are also given.

The reclamation of the Zuider Zee, J. M. FIGEE (Engin. News, 72 (1914), No. 16, pp. 778-780, figs. 2).—A system of reclamation by means of dikes and steam pumping plants whereby about 800 square miles will be drained and made available for agricultural purposes is described and illustrated. It is estimated that this project will cost about \$130,000,000 and will require 33 years for completion.

The cost of tile drainage: A study of the cost of installing thirty-five miles of tile drains on a farm in Huron County, Ohio, L. H. Goddard and H. O. Tiffany (Ohio Sta. Circ. 147 (1914), pp. 21-44, figs. 7).—This circular pre-

sents an approximately accurate record of the expense of the various operations performed in installing 11,395 rods of tile for the purpose of draining areas totaling 228 acres.

The work was done in part by hand trenching and in part by machine trenching. Practically all the soil of the farm is of glacial origin and the principal type is clay loam containing a large percentage of silt. The surface soil consists of clay or heavy silt loam about 9 in, deep, which gradually becomes heavier with the depth until at 18 to 24 in, it is a clay which becomes decidedly plastic at a depth of 3 ft. The lower lying soil consists mainly of a dark-colored clay loam or clay, varying greatly in depth and underlain by a very stiff blulsh clay.

The tiling operations of the first year were largely contined to hand trenching, while the work of the other two years was mainly done by machine trenching. The power tile ditching machine used was equipped with a caterpillar tractor. The machine was equipped to do work at four different rates of speed which were used according to depth of digging and stickiness of dirt. Dry ground had no effect upon the machine except to dull the knives, and soil frozen to a depth of 4 in, and the freezing of wet earth to the machine caused little trouble. During the greater part of the season the machine could be operated satisfactorily immediately after heavy showers. Round stones or boulders in the ditch line caused more or less trouble, depending upon the location in the ditch, the size of the stones, etc. Boulders the size of a man's head were removed by the machine with comparative case but when larger than this it was necessary to raise the digger wheel and remove them by hand.

A comparison of machine trenching with hand trenching shows the former to have an advantage in cost of 7.4 cts. per rod. Another point in favor of the ditching machine is the speed which can be maintained, it being shown that the machine operators use less than one-sixth as much labor per rod in trenching and laying tile as is spent when the work is done by hand. "Considering the scarcity of labor and the advancing wages that farmers are being forced to pay, it is evident that, even though machine trenching were to cost more than hand trenching, they probably would be forced to make use of the machine."

A summary of the costs of all tiling operations except hauling is given in the following table:

| Installina co | sts ner | rod o | f tile dra | inage bu | hand an | d machine. |
|---------------|---------|-------|------------|----------|---------|------------|
|---------------|---------|-------|------------|----------|---------|------------|

| | Handwork, 1909. | Machine, 1910. | Machine, 1911. | Average machine. |
|---|--------------------|--------------------------------------|--------------------------------------|--------------------------------------|
| Area in acres. Number rods dug. Machine charges. Machine operator. | 2,560 | 65½ 4,080 80.1084 .0315 | 122½ 4,755 \$0.1529 .0392 | \$0.1324 .0356 |
| Gasoline. Oil. Contract laying. | \$0.3760 | .0219 .0014 .0634 | .0305 .0028 .0686 | . 0266 . 0022 . 0663 |

Report of the investigations on drain tile, American Society for Testing Materials (*Iowa Engin. Expt. Sta. Bul. 36 (1914*), pp. 110, figs. 3).—Tests of clay and concrete tile to determine the comparative values of results secured by the use of sand bearings, hydraulic bearings, and three-point bearings are

reported, the test specimens consisting of 100 each of 8-in., 16-in., and 24-in. tile of each material. *

The general conclusions drawn are that the results of the tests by each of the types of bearings are consistent and concordant, and apparently reliable and truly indicative of the quality of the tile. The numerical results by the different bearings have fairly uniform ratios and can be calculated and reported in substantially the same unit by multiplying the breaking loads per lineal foot by the following factors; Sand bearings, 1; hydraulic bearings, 1.25; and three-point bearings, 1.5.

The sand bearings required from one to seven minutes more per test than the other bearings but are said to come much nearer to giving the real supporting strength of the tile in the ditch. The hydraulic bearings distributed the load very well along the tile to tit irregularities in shape and permitted rapid testing. The three-point bearings are considered the simplest and most convenient of all to use.

"There can not be nearly so wide a variation of the 'ordinary supporting strength' of drain tile in ditches, to carry the loads from the ditch filling as has heretofore been very generally assumed. . . . A comparison of the loads from ditch filling with the results of laboratory tests . . . indicates that the 'ordinary supporting strength' of drain tile in ditches is approximately equal to the breaking loads in tests with sand bearings." Additional tests of the same nature are reported which confirm the above conclusions.

A comparison of actually weighed values of loads on pipes in ditches from the weight of ditch filling with those computed from the formula $W_F = CwB^2$ shows a correspondence between the computed and weighed loads, thus closely checking the correctness of the formula. In this formula W_F =the load on a pipe in a ditch in pounds per lineal foot, from the weight of ditch filling, C=the coefficient, taken from a proper table or diagram, of loads on pipes in ditches from ditch filling, w=weight of ditch filling material in pounds per cubic foot, and B=the breadth of the ditch, a little below the top of this pipe, in feet.

Investigations of factors of safety in actual tile drains and pipe sewers where the pipe have actually been observed to be sound resulted in the conclusion that with so-called "first class" pipe laying conditions, corresponding to the best pipe laying practice, and watched constantly by an inspector, it will be safe to use a nominal factor of safety of 1.25. For "ordinary" pipe laying conditions the factor of safety should be 1.5.

Other sections give data on the manufacture of the concrete tile tested and on the calculation of the modulus of rupture of the material of the tile shells. The formulas resulting from the latter calculation are: $M=0.20R\frac{W}{12}$, and $p=\frac{6\,M}{t^2}$, where M=the maximum bending moment in the tile shell, in inchpounds per lineal inch, R=the radius of the center line of the tile shell, in inches, W=the "ordinary supporting strength" of the tile, in pounds per lineal foot, calculated by multiplying the breaking loads in strength tests by the factors noted above (five-eighths the weight of the tile per lineal foot for sand bearings, or three-fourths for hydraulic or three-point bearings, must be added to W in computing M whenever such addition exceeds 5 per cent of W), p= the modulus of rupture of the material of the tile shell, in pounds per square inch, and t=the average thickness of the tile shell, in inches, at the top or the bottom, whichever averages thinner.

Tile investigations, W. H. DAY (Ann. Rpt. Ontario Agr. Col. and Expt. Farm, 39 (1913), pp. 56-64, figs. 5).—Comparative tests of the breaking strength of 3 and 4-in. cement and clay tile showed that the average breaking strength

of the cement was 10 lbs, more than that of thin clay tile, and 333 lbs, less than average clay tile. It is concluded, however, that any of the clay or cement tile tested were strong enough to resist the earth pressure to which they would be subjected if placed in the ground. Further comparative tests of machinemade cement tile and clay file led to the conclusion that cement tile, if properly made and cured, are as strong as some well-known and satisfactory makes of clay tile and strong enough for tile drainage purposes.

Tests of the immersion in air, immersion in vacuum, and specific gravity methods for determining the porosity of tile showed that the vacuum and specific gravity methods give almost identical results, which are both more than one-tifth higher than by immersion in free atmosphere. Using the immersion in vacuum method, it was found that the porosity of well-made cement tile was on the average considerably less than that of clay tile. It was also found that porosity of the tile wall was not the governing factor in permeability, this depending more on the glaze of the surface.

Tests of the permeability of cement and clay tile showed the clay tile, although more porous than the cement tile, to be usually less permeable. The cement tile, however, showed considerable difference of behavior which depended on the wetness of the mortar, it being found that if the mortar was wet enough so that the packer produced a smooth watery surface on the entire inner surface the tile wall was practically water-tight.

Proportioning aggregates for Portland cement concrete, A. Moyer (Reprint from Amer. Soc. Testing Materials Proc., 14 (1914), pp. 12).—This paper describes various methods of carrying on investigations so that with a given sand and a given stone or gravel, proportions can be stated by the engineer which will make a concrete of maximum density and maximum strength. Investigation showed that arbitrary specifications without previous knowledge of the character of the aggregates are likely to be wrong.

It is concluded that it takes 110 lbs. of Portland cement to make 1 cu. ft. of paste in opposition to the usual assumption of 94 lbs. per cubic foot. The author further concludes that instead of the old plan of filling the voids with sand and cement these voids must necessarily be filled with paste (cement and water), and that the study of the proportioning of aggregates must be based on the proper proportions of cement, water, and sand to make a sufficiently rich mortar to bind together the larger aggregates.

For the purpose of economy it is stated that various sizes of stone should be used and an investigation made to determine which size will produce the least percentage of voids so that less mortar may be used and more strength obtained.

Specifications for sand for concrete, E. McCullough (Cement Era, 12 (1914), No. 10, p. 56, fig. 1).—The author "as a result of many hundred granulometric analyses of concrete sand proposes the following specification as suitable for general use and which will not bar out any good sand to be found on the market:

"The sand may be any suitable material of a quality at least equal to the quality of the stone or gravel used in the concrete and shall range in size from fine to coarse. It shall all pass through a 4-in, mesh; not to exceed 80 per cent shall pass through a 20 mesh; not to exceed 50 per cent shall pass through a 50 mesh; and not to exceed 20 per cent shall pass through an 80 mesh."

[Land clearing], J. H. Grisdale (Canada Expt. Farms Rpts. 1913, pp. 26-28).—Twenty acres of land covered with heavy timber were cleared under provincial conditions for the plow at an average cost of \$506 per acre. The windfalls, trees left by loggers, and brush were cleared away before attacking the standing timber.

Fifty-eight acres were cleared under contract, the following comparisons being made: Twenty acres of swampy ground were cleared with a 40-horsepower donkey engine at a total average cost of \$398 per acre. Twenty acres with no swamp were cleared by "a practical man with a good crew and teams" at a cost of \$338 per acre. The total cost per acre of clearing seven acres of similar land which had previously been slashed was \$246, and of seven acres previously cleared of brush by a forest fire \$189. Four similar acres were cleared by a crew, stump puller, and team at a cost of \$212 per acre.

Two trials of the charpit system were unsuccessful, owing to heavy rainfall. Two tests, made on two large stumps standing side by side to see whether, by running a cable from each to a 7-ft, stump and tightening it by wedges, the side tension would help in pulling the stump clear of the ground when blown up, were unsuccessful.

Stump burning to reclaim logged-off lands, Le R. W. Allison (Engin. Rec., 70 (1914), No. 4, pp. 95, 96, fig. 1).—Methods and costs of clearing tracts of fir and pine stumps for agriculture in the Pacific Northwest are given. The burning out of the roots by charpitting is said to be the most favored method. A plant for this purpose is described, which consists of a gasoline engine, a 5-fire stump burner, a cordwood saw, a power grubber, a geared horse stump puller, and a power stump puller.

Annual report of the state highway department (Ann. Rpt. State Highway Dept. Ohio, 8 (1912), pp. 276, figs. 136).—This includes the reports of the bureaus of construction, maintenance and repair, and bridges, and of the state testing laboratory. A number of plans and illustrations accompany these reports.

In a report on the road materials of Ohio, sedimentary rocks are said to predominate and are represented by the following varieties: Shale, sandstone, limestone, dolomite (dolomitic or magnesian limestone), conglomerate, underclay, fire clay, chert or flint, coal, iron ore, clay, sand, and gravel.

Additional rules and regulations governing state road work for year 1913 (State Highway Com. Minn. Bul. 10 (1913), pp. 8, pls. 6).—Detailed plans and working data for plain and reinforced highway culverts are given.

Standard culvert designs (Cement Era, 12 (1914), No. 10, pp. 51-53, 63, figs. 13).—Standard plans, together with quantities of material and reinforcing, are given for different sizes of circular concrete culverts as designed by the Iowa Highway Commission.

Some tests on a Diesel engine, W. S. Burns (Gas Engine, 16 (1914), No. 10, pp. 615-621, figs. 11).—Tests on the effect of (1) variation of blast pressure and (2) variation of jacket water temperature upon the running of a Diesel engine are described and the results reported graphically.

It was found that at all loads too low a blast pressure pulverizes the oil imperfectly, causing late ignition and incomplete combustion with increase of exhaust pressure and temperature above normal, while too high blast pressure causes late but violent ignition attended again by incomplete combustion of the oil. At all loads an increase of jacket water temperature did not seem to affect the point of ignition of the oil appreciably, but caused more rapid and more complete combustion with increased efficiency.

A rating chart for centrifugal pumps, L. J. Beadford (Engin. News, 72 (1914), No. 8. pp. 382-384, figs. 4).—A graphical rating table is given to facilitate the selection of pumps when the speed, head, and capacity are given.

The present status of mechanical cultivation in Europe, F. Ledeboer (Meded. Procestat. Java-Suikerindus., 4 (1914), No. 25, pp. 491-520, pls. 23; Arch. Suikerindus, Nederland. Indië, 22 (1914), No. 19, pp. 689-718, pls. 22).—A large number of mechanical cultivating machines, grouped under the two

types, tractors and cable systems, are described and illustrated and their methods of operation discussed.

Preliminary tests of new dairy machinery, B. Martiny (Arb. Deul. Landw. Gesell., No. 259 (1914), pp. 69, figs. 18).—A large number of different dairy implements are described and illustrated, and preliminary tests of the systems as to the manner and efficiency of their operation are reported.

The distribution of the overhead electrical discharge employed in recent agricultural experiments, I. JÜRGENSEN and J. H. PRIESTLEY (Jour. Agr. Sci. [England], 6 (1914), No. 3, pp. 337-348, figs. 8).—In studies of conditions requiring certain modifications in the methods to be employed in subsequent field experiments it was found that the strength of the discharge from an overhead wire network at a high potential is a variable quantity depending on the mobility of the carriers of the electricity and on the velocity of the wind,

Measurements of potential gradient and of current density agreed in showing that the effect of the discharge is not limited to the area under the wires, which is of importance owing to the fact that control and electrified areas have usually been placed close together in field experiments. In this connection an account is given of the distribution of the discharge under various weather conditions. Methods are discussed by which the control area may be kept under more normal electrical conditions in spite of the proximity of the overhead discharge wires, and the results of more or less unsuccessful experiments in this direction in which a plat was entirely inclosed by a wire cage of ½-in, mesh netting 6 ft, high are discussed.

Farm storages for fruits and vegetables, E. Smith (Brit. Columbia Dept. Agr. Bul. 58 (1914), pp. 27, figs. 18).—This bulletin deals with storages for fruits and vegetables.

The two main types dealt with are those using some means of lowering the temperature below that of the outside air and those depending upon temperatures secured from atmospheric changes. The first class is subdivided into those using mechanical refrigeration and those using ice as a refrigerant. The desirable points taken from many designs investigated are summarized in diagrammatic illustrations which are intended for complete and modern cold storage and packing houses.

It is stated that with a basement storage better ventilation is had by placing the building at right angles to the prevailing winds, and if the storage is above ground the building should run north and south. For vegetable storage the cheapest equipment to supply is said to be the pit or trench, in which may be stored such crops as the potato, cabbage, celery, carrot, beet, and other root crops. Good drainage is essential for a storage pit of this kind, and this may usually be found on a slope having a loose or gravelly subsoil.

Bills of material are given for different types of storage structures and special information is given for storage houses for celery and onions.

The geology of the county of Jervois, and of portions of the counties of Buxton and York, with special reference to underground water supplies, R. L. Jack (Geol. Survey So. Aust. Bul. 3 (1914), pp. 47, pls. 6, figs. 4).—This report describes and discusses the topography and geology of the county of Jervois and portions of the county of York, with special reference to the occurrence and distribution of surface and underground water supplies. A geological chart of the area is appended.

Lowering of the ground-water table, W. A. Cook (*Trans. Kans. Acad. Sci.*, 26 (1913), pp. 84–86).—The drying up of creeks, ponds, rivers, surface springs, and wells in eastern Kansas is attributed by the author to the lowering of the ground-water table in that part of the State. It is stated that stockmen, farm-

ers, and municipalities should seek a water supply well below the present water table.

"Witching" for water and other things, J. T. LOVEWELL (Trans. Kans. Acad. Sci., 26 (1913), pp. 101-103).—The author concludes "that all the claims of water witches are delusions unworthy scientific consideration."

Analyses of private water supplies, H. E. BARNARD, J. A. CRAVEN, and J. C. Digos (Ind. Bd. Health, Ann. Rpt. Chem. Div., 8 (1913), pp. 297-333, figs. 22).—Analyses of a large number of private water supplies from wells, springs, and cisterns show that the deep well waters were in most instances of good quality. The shallow-dug well waters were in nearly all cases bad or doubtful, as were also the majority of the cistern and spring waters examined. A number of photographs of bad conditions existing in the immediate vicinity of wells, springs, and cisterns are included.

The water supply of farm homesteads, F. T. Shutt (Canada Expt. Farms Rpts. 1913, pp. 225, 268-275).—Of 188 samples of water from various parts of the Dominion submitted to complete sanitary analysis 89 were pure and wholesome, 43 suspicious and probably dangerous, 41 severely contaminated, and 15 too saline to be used as a potable supply. The worst waters were from shallow wells dug in barnyards or in the neighborhood of similar sources of pollution.

Illuminating power of kerosenes, W. Kunertii (Iowa Engin. Expt. Sla. Bul. 37 (1914), pp. 29, figs. 6).—A series of experiments conducted to determine the quality of kerosene oils used in the State of Iowa and the relations existing between the illuminating power of a kerosene oil and some of its physical properties are reported. Sixty-one samples of kerosene were tested.

By the application of ordinary photometric methods great differences in the illuminating power of different samples of kerosene oils were shown. Oils having a high illuminating power were found also to be high in density, index of refraction, viscosity, surface tension, flash point, and burn point. With these oils the length of wick charred was shorter and the fogging of the chimney was more marked than for the oils of low illuminating power.

Putting coloring matter into the oil and exposing it to light and draft reduced the illuminating power. The denser the oil the greater was the intrinsic brilliancy of the flame, and the lighter the oil the more nearly white was the flame.

It was further shown that the oils used in Iowa have practically the same burning quality, that oils from the East have a lower density and are sold at a higher price, and that oils which were retailed at a lower price gave the most light.

It is concluded in connection with these tests that kerosene oil lamps are not very desirable as standards of comparison.

RURAL ECONOMICS.

What the farm contributes directly to the farmer's living, W. C. Funk (U. S. Dept. Agr., Farmers' Bul. 635 (1914), pp. 21, figs. 2).—This contains the result of a study to determine the value of that part of the farmer's living which is furnished directly by the farm. The practice was to drive along a road in the district selected and visit every farmhouse, the aim being to obtain a true average for the conditions of that community. The regions studied include counties in North Carolina, Georgia, Texas, Kansas, Iowa, Wisconsin, Ohio, Pennsylvania, New York, and Vermont, and deal with 483 farmers having an average of 4.6 persons to a family.

It was found that the average annual value of food, fuel, and use of a dwelling as furnished by the farm were \$421.17 per family, \$261.35 being for food, \$34.72 for fuel, and \$125.10 for house rent. The average value of the food,

coal, wood, and oil bought per family was \$173.91, of which \$150.75 was for food, \$14.79 for coal, \$2.63 for wood, and \$5.74 for oil. Of the food consumed per family 63 per cent was furnished by the farm, of the groceries 5.6 per cent, of the animal products 83.5 per cent, of the fruits 66.6 per cent, and of the vegetables 78.2 per cent. The average annual value of the use of the farmhouse was found to be \$125 per family.

The author concludes that "the result of these studies shows that the farmer's cost of living in actual cash expenditures is very materially reduced by what the farm furnishes in food products, fuel, and house rent; in fact, the income from this source adds as much to the real wealth of many farmers as does the net income from the sale of farm products."

A large number of tables are included showing the variations in the different States studied, and details for the various items included under the general classes mentioned above.

The work of rural organization, T. N. Carver (Jour. Polit. Econ., 22 (1914), No. 9, pp. 821-844).—The author points out that after an agricultural region has once become settled, with all the land in cultivation and with enough labor employed on it to cultivate it somewhere beyond the point of diminishing returns, it must limit its birth rate and keep the population stationary; increase the intensity of its cultivation, getting continually smaller production per man, though increasing the production per acre; or force its surplus rural population to migrate either to new agricultural regions or to cities. He also points out that if prices fall not only must the farmer reduce his yields per acre, but his acreage if he would avoid bankruptcy.

With the improved methods of farming, a farmer has greater need of capital and, therefore, of credit, but credit should be employed only where it gives the greatest productive advantage. When it comes to the work of growing farm crops as distinct from selling them and buying the raw material, the one-family farm is the most effective unit but to buy or sell effectively the large producer has an advantage, and individual farmers should unite to obtain the same advantage. The principal lines of work along which farmers should organize are the growing of farm products, purchasing farm supplies, securing adequate credit, and improving the means of communication and transportation. To make the farmers' living conditions better an improvement in the education, sanitation, recreation, and beautification in rural districts is necessary.

Unifying rural community interests, edited by H. ISRAEL (New York and London, 1914, pp. 125).—This book contains a series of addresses on the following subjects: The Department of Agriculture and Country Life and The United States Rural Organization Service, by T. N. Carver: The Point of Emphasis in the New Rural School Idea, by A. C. Monahan; The Country Church and the Young Men's Christian Association, by G. W. Fiske; and The Place of the Young Men's Christian Association in the New Rural Awakening, by K. L. Butterfield.

Bibliography of rural sociology (N. H. Col. Agr. and Mech. Arts, Bibliogr. Rural Sociol., 1914, pp. 8).—This pamphlet contains a brief, annotated bibliography.

Proceedings of the seventeenth conference for education in the South (*Proc. Conf. Ed. South. 17 (1914), pp. 386, pl. 1, fig. 1*).—This conference has been noted editorially (E. S. R., 30, p. 608).

Syllabus of home-study club studies (*Univ. N. C. Rec.*, *No. 121* (1914), pp. 43).—This syllabus outlines a method for the home study of conditions within a county by means of a series of questions, and points out how to obtain answers to the questions—Among the topics outlined are natural resources, popu-

lation, wealth studies especially from farm products, rural credits, markets, highways, schools, public health, the church, and the farm home.

Cooperative institutions among the farmers of Catawba County (Univ. N. C. Rec., No. 119 (1914), pp. 15).—This pamphlet tells how a cooperative creamery, a sweet potato growers' association, a farmers' union warehouse company, and a rural credit association were organized.

The influence of social position of members of cooperative societies upon their activities in relation to agricultural saving and loan banks, J. ZIMMER (Landw. Jahrb., 46 (1914), No. 3, pp. 431-454, figs. 2).—The author calls attention to the organization of cooperative societies and banks, the methods of creating working capital, and the employment of the capital as the system is influenced by social status of the members of the society, i. e., as to whether they belong to the agricultural, industrial, or commercial classes.

Cooperative credit (Bul. Russell Sage Foundation Libr., No. 5 (1914), pp. 7).—This pumphlet contains an annotated bibliography on cooperative credit.

Newark Horsekeepers' Insurance Company, Limited (Jour. Ed. Agr. [London], 21 (1914), No. 7, pp. 644-652).—In this company the horses insured are revalued each year in December, and the amount of the valuation determines for the next 12 months the amount payable on any claim regarding the horse. In case of loss the company pays only two-thirds of the market value. The rate of insurance charge is approximately 5\(\frac{5}{2} \) per cent per annum of the market value, and this also entitles the insurer to attendance and medicine by a veter-inarian employed by the company.

Economic history [of agriculture] in Russia, J. Mavor (In An Economic History of Russia. London, Toronto, and New York. 1914, vol. 1, pp. 185-430; rev. in Scot. Geogr. Mag., 30 (1914), No. 10, pp. 518-527).—These chapters are devoted to a discussion of the Russian agricultural peasant and describe the various types found, with a history of the movement from the beginning of the eighteenth century to date.

The agricultural labor conditions in Russia, S. Blank (Die Landarbeiterverhältnisse in Russland seit der Bauernbefreiung. Zurich and Leipsic, 1913, pp. 226, pl. 1, figs. 3).—This book discusses the economic status of the Russian peasantry, the various types of agricultural laborers, their wages, living conditions, and the attitude of the government toward them.

Slavs on southern farms, L. Hodges (U. 8. Senate, 63. Cong., 2. Sess., Doc. 595 (1914), pp. 21).—The author describes the success of the Poles and Bohemians as farmers in Texas, Arkansas, and Virginia. He declares that they have made good as farmers in communities where the native Americans are scarcely able to maintain themselves, and that they have been found to be thrifty, industrious, and thoroughly honest in all their business and social relations.

The agrarian revolution in Georgia, 1865–1912, R. P. Brooks (Bul. Univ. Wis., No. 639 (1914), pp. 129, figs. 5).—The author traces the history of the negro as a farm laborer and share tenant. He concludes that it is the escaping from supervision, and not the larger opportunity for profits, that the negro has in mind in shifting from the position of wage earner or share tenant to renter.

The history of the normal negro agricultural laborer is stated as follows: He begins as a youth working for wages. As soon as he has a family that can be utilized for field work he becomes a share tenant. Under the semicompulsion of this system he makes good profits, and, if he has any capacity for saving, can in a short time buy a mule and a few tools and set up as a renter. So great has been the competition for laborers and so completely have the negroes had the upper hand in this matter, that negro wage earners and share tenants have in many instances been able to achieve an independent position even

without the inconvenience of having to save the small amount necessary to stock a renter's farm.

The author also calls attention to the variations from this process under the different geographic and economic conditions found in Georgia.

Penal farms and farm colonies (Bul. Russell Sage Foundation Libr., No. 6 (1914), pp. 4).—This bulletin contains a brief, annotated bibliography.

[Statistical record of agricultural progress in the United States] (*U. S. Dept. Com., Statis. Abs. U. S., 36 (1913), pp. 120–181. 229–240).*—Contained in this annual statement are statistical data showing for the United States the number of acres in farms, the area of improved and unimproved land for 1890, 1900 and 1910 by States, the area, production, and value of the principal farm crops by States for 1912–13, and for the United States as a whole for 1860–1913, the number of live stock for the United States as a whole, 1889–1913, the quantity of animal products manufactured for the census years 1850 to date and of forestry products for 1908–1913, inclusive, and the number of persons employed in specified gainful occupations for 1910.

Field agent's handbook of agricultural statistics (U. S. Dept. Agr., Field Agent's Handb. Agr. Statis., 1914. pp. 116).—This handbook, intended for ready reference, contains in condensed form statistics of the important classes of agricultural products for the United States and for each State, showing the acreage and value of the principal farm crops, number and value of animals sold or slaughtered, and quantity and value of animal products sold.

The agricultural outlook (U. S. Dept. Agr., Farmers' Bul. 641 (1914), pp. 1–9, 23–40, fig. 1).—This report gives the usual information regarding the estimated average yield per acre, total production, quantity, and price of the principal farm products, including comments on the preliminary estimates of several crops by F. Andrews and the world's wheat outlook by C. M. Daugherty. Statistical data are also given showing the hops consumption and movement in the United States for 1906–1914. This data indicates that the total consumption by brewers and exports amounted to 68,280,743 lbs. in the fiscal year ended June 30, 1914, of which 5,382,025 lbs. were imported.

Preliminary reports are also included as given by the International Institute of Agriculture concerning the production of specified crops in specified countries and from the Government of Canada concerning the production of farm crops for 1914.

Statistical tables showing the condition, yield per acre, production, quality, price, weight of grain per measured bushel, and stocks on farms of specified crops, by States, and other data are appended.

Range of prices for butter and eggs in the Chicago market together with the receipts, also prices for refrigerator eggs (*Chicago*, 1914, pp. 16).—This contains data as to the monthly receipts at the Chicago market of butter and eggs for the past 10 years, the monthly prices for the past 20 years, and a classification of the various grades of butter and eggs.

Wholesale prices, Canada, 1913, R. H. COATS (Canada Dept. Labor, Wholesale Prices, Canada, 1913, pp. XVII+288, figs. 22).—This report shows the wholesale prices by months, beginning with 1890, for practically all the products of the farm.

[Management of the Central Experimental Farm, Ottawa, Canada] (Canada Expt. Farms Rpts. 1913, pp. 32, 33, 113-122, pl. 1).—This report gives a statement of the crop returns on the Central Experimental Farm for 1912 together with the value per unit for the different items of cost as well as the products obtained. The statement also includes the rotations followed and the yields. These details are shown by means of statistical tables,

Occupations and industries (*Census of England and Wales*, 10 (1911), pts. 1, pp. CL1+867; 2, pp. VIII+781).—These volumes of the census give the number of persons engaged in agriculture and other occupations by sex, age, marital conditions, and position held, for England and Wales as a whole and by minor geographic divisions. It was found that the number of males and females employed in agriculture formed a decreasing proportion of the total population as indicated in the following table.

Number of persons engaged in agriculture in England and Wales, 1851-1911, and the proportion of the total population.

| Census year, | Males aged 10 years and up- ward engaged in agriculture. | Proportion of total males aged 10 and upward. | Females aged 10 years and upward en- gaged in agri- culture. | Proportion of total fe- males aged 10 and upward. | |
|--|---|--|---|--|--|
| 1851 1861 1871 1871 1881 1894 1901 | 1,233,936 | Per cent. 23.5 21.2 16.8 13.8 11.6 9.5 9.2 | 168, 652 115, 213 85, 667 64, 216 51, 045 38, 782 37, 969 | Per cent, 2.4 1.5 1.0 .6 .4 3 .3 | |

The number employed in agriculture, the total acreage under crops and grass, and the number of the different kinds of live stock have remained practically the same during the last 30 years.

Statistical abstract for the British Empire in each year from 1898–1912 (Statis. Abs. Brit. Empire, 10 (1898–1912), pp. 241–290).—Contained in this report are statistical data showing the production and consumption of the principal agricultural products in the United Kingdom and its various colonies and possessions for 1912, with comparative data for earlier years.

Statistical abstract for the principal and other foreign countries in each year from 1901–1912 (Statis. Abs. Prin. and Other For. Countries [Gt. Brit.], 39 (1901–1912), pp. 358–380, 466–472).—This report contains statistical data showing the total arable or cultivated land, the acreage and production of the principal farm crops, and the number of live stock for as many countries as information is available. It shows the quantity of beets used by sugar factories, the sugar produced, and the quantity imported, exported, and consumed.

Statistics of harvest in Austria, 1913 (Statis, Jahrb. K. K. Aekerb. Min. [Austria], 1913, pp. VI+360).—This yearbook gives the area devoted to various agricultural purposes, the area in crops, and the average and total yields by minor geographic divisions.

Agricultural statistics of Italy (Ann. Statis. Ital., 2. ser., 3 (1913), pp. 130-144).—This portion of the annual statistics of Italy shows the area devoted to the different agricultural purposes by Provinces and the total areas and production of the principal crops for 1913, with comparative data for earlier years.

AGRICULTURAL EDUCATION.

The training of women in the state colleges, Margaret B. MacDonald (Rural Educator, 4 (1914), No. 3, pp. 50, 51).—Attention is called to the opportunities for women to study agriculture and home economics at the state agricultural colleges.

Teachers' extension schools, G. A. Bricker (Rural Educator, 4 (1914), No. 1, pp. 6-9, figs. 2).—This article has been previously noted (E. S. R., 27, p. 195) with the exception of an added scheme for the establishment of a system of teachers' extension schools, taking the county as a unit, in any State.

Agriculture in the high school and community service, G. A. Works (Bul. Univ. Wis., No. 591 [1913], pp. 70-73. fig. 1).—In this paper, presented at the third annual Wisconsin Country Life Conference in January. 1913. the author suggests opportunities for community service by the high schools giving instruction in agriculture.

Rural schools linked up with home and farm, ELLEN B. McDonald (Bul. Univ. Wis., No. 591 [1913], pp. 73-81, fig. 1).—In this paper, presented at the third annual Wisconsin Country Life Conference in January, 1913, the author points out opportunities in country schools for practical work related to the farm and the home in civics and history, arithmetic, language, hygiene, geography, agriculture, boys' and girls' farm contests, harvest festivals in schoolhouses, sewing, and industrial work.

Agriculture in the Idaho Falls high school, B. R. CRANDALL (Amer. School Bd. Jour., 49 (1914), No. 4, pp. 17, 18, figs. 4).—A description is given of the 4-year agricultural course, which is cultural as well as vocational. A short winter course in English, farm accounting, general agriculture, irrigation farming, dairying, and farm repairs is also offered for boys unable to take the longer course.

Boys' and girls' demonstration work in the Southern States, O. B. MARTIN (Proc. Conf. Ed. South and Ann. Meeting South. Ed. Assoc., 1914, pp. 57-62).—This is a review, including the best individual and collective records, of the girls' canning club and boys' corn club work in the Southern States in 1913.

School gardens (Allantic Ed. Jour., 10 (1914), No. 1, pp. 26-30).—A survey of experiments in community work among school children that are being tried in various sections of the country.

Gardening in public schools, H. P. Williams (*Breeder's Gaz.*, 66 (1914), No. 6, pp. 187, 188, figs. 4).—General notes on boys' and girls' club work are followed by an account of the school garden work in Cook County, Ill., by E. J. Tobin and S. Shepard.

The Portland school gardens, M. O. Evans, Jr. (Amer. School Bd. Jour., 49 (1914), No. 1, pp. 36, 37, figs. 2).—A brief description is given of the 43 school gardens in Portland, Oreg., covering a total area of approximately 16 acres. A total of 10,600 children are participating in school and home gardens, or 39 per cent of the total public school enrollment.

[Instruction in agriculture and home economics in Alaska] (*U. S. Bur. Ed. Bul., No. 36* (1913), pp. 19–30).—Reports by teachers in the public schools under the control of the Federal Government include notes on instruction in agriculture, cooking, sewing, and laundering.

The folk high schools of Denmark, L. L. Friend (U. 8. Bur. Ed. Bul. 5 (1914), pp. 24+111, pls. 4).—The author gives a brief historical sketch and describes the organization and work of the folk high schools of Denmark, points out what they have accomplished for Denmark, and offers suggestions as to the possible application of the folk high school idea in the mountain and Piedmont sections of the South in this country. As in Denmark, the special mission of such schools would be to offer short winter courses to young men and women between the ages of 16 and 25 or 18 and 30, to awaken their intellectual life and give them technical instruction in the pursuits of rural life. A suggested program for a course for young men, covering three winter terms of five months each, is outlined.

The Danish folk high schools, H. W. FOGHT (U. S. Bur, Ed. Bul, 22 (1944), pp. 93+11, pls. 6).—In this bulletin, which is an amplification of that previously noted (E. S. R., 31, p. 598), the author discusses recent agricultural evolution, the evolution of the folk high school in Denmark, how the school is organized and administered, and the subject-matter and its presentation. He also describes some typical folk high schools, local agricultural schools and their work, special agricultural schools for small holders, rural schools of household economics, and the folk high school transplanted to other countries. cussing the feasibility of adapting the folk high schools to American conditions he considers the need of agricultural reorganization in this country, the inability of the old rural schools to cope with the situation, the coming of the centralized farmers' schools, how the reorganized schools may profit by the Danish system, why there is need of schools for grown-ups in the United States, the South Atlantic Highlands as a good place to begin, the "moonlight" schools of Kentucky, how the schools which should receive all who are not now looked after by the public schools might be organized, and schools in which to train the teachers.

Agricultural education in the State of Victoria, Australia, E. HANDLEY (Rural Educator, 4 (1914), No. 1, pp. 17, 16).—A topical outline of the course in agriculture in the third and fourth years in the agricultural high schools.

[Nature study and elementary agriculture for the New York public schools] (Cornell Rural School Leaflet, 8 (1914), No. 1, pp. 276, pl. 1, figs. 46).— This consists of two parts, as follows: (1) Subject matter of help in teaching nature study and elementary agriculture as outlined in the New York state syllabus for 1914–15, comprising articles by specialists on birds, animals, plants, insects, and trees; and (2) suggestive material for rural teachers especially interested in out-door study, including several special articles and rural teachers' reports on the teaching of nature study and elementary agriculture.

Nature study and agriculture course for use in the public schools of New Brunswick, R. P. Steeves (Fredericton, New Brunswick; Bd. Ed., 1914, pp. 32).—This contains a syllabus of a course of instruction in nature study and agriculture for grades 1 to 8, inclusive, approved by the board of education April 23, 1914; suggestions on methods of teaching; subject-matter classified under the headings of plants, animals, physical nature, and environment, and arranged by months for each of the first five grades; a list of books recommended as helpful in teaching nature study and agriculture; and the board's regulations governing the instruction in elementary agriculture with school gardening.

Agricultural education (Dept. Agr. New Brunswick Bul. 2 (1914), pp. 13, figs. 4).—Suggestions to teachers concerning subject-matter in agriculture and school gardening for the months of January to June, inclusive, and methods of teaching these subjects.

[Agricultural instruction for the teachers of Porto Rico] (Agr. Col. Weekly [P. R.]. 2 (1914). Nos. 71, pp. 353-356; 72. pp. 357-362, figs. 3; 73. pp. 363-366; 74, pp. 367-370; 75. pp. 371-376; 76, pp. 377-380; 77. pp. 381-384; 78, pp. 385-388; 79. pp. 389-393, figs. 3; 80, pp. 394-399).—These bulletins consist of studies of poultry growing in the Tropics, the prunning of trees, coffee growing. physics as a practical study, ginger and its cultivation, diversified farming, coconut culture, patterns and models, and some problems in feeding poultry.

The natural history of the farm, J. G. Needham (Ithaca, N. Y., 1913, pp. 348, figs. 140).—This book on the sources of agriculture offers a series of studies for the entire year, each dealing with a different phase of life on the farm and each made pedagogically practical by a definite program of work. A definite form of record is suggested for each practical exercise illustrating field work methods. Individual exercises which the student may pursue independently, as

well as a chapter on the production and preservation of wild nature, are included.

A suggestive outline for work in the study of soils, L. G. ATHERTON (Normal Teacher [Madison, 8, Dak.], 3 (1913), No. 2, pp. 9).—Practical exercises in soil study, together with suggestions for carrying them out in rural schools, are given.

Dry farming in Oregon, H. D. Scudder (New York, 1914, pp. 19, figs. 7).—This supplement to Warren's Elements of Agriculture (E. S. R., 21, p. 494) is a study of dry farming conditions, special tillage practices, machinery, crops, and farm management in Oregon.

Demonstration work for agricultural high schools, J. T. West (Miss. Agr. Student, 2 (1914), No. 2, pp. 6, 5).—Methods for planting agricultural high school demonstration plats in a three-year rotation are outlined.

Corn, M. J. Abbey (W. Va. School Agr., 5 (1914), No. 1, pp. 18, figs. 8).—In this series of field and classroom lessons on corn the facts are developed largely through the pupils' own activity, the teacher being merely the guide to the information. Suggestions on how to correlate the study of corn with other school subjects are given.

The home vegetable garden (Cornell Rural School Leaflet, 7 (1914), No. 4, pp. 293-301, figs. 5).—A complete vegetable garden plan is outlined as a guide for older boys and girls, together with a few general rules for gardening.

Transplanting, R. T. Neal (Hampton Leaflets, 1 (1914), No. 3, pp. 12, figs. 6).—The author gives reasons and instructions for transplanting plants.

Fall work with apples, M. J. Abbey (W. Va. School Agr., 5 (1914), No. 2, pp. 16. figs. 9).—The author sets forth some of the elementary principles of apple culture and outlines exercises indicating how this subject-matter may be taught by demonstrations, trips to the orchard, and inquiries by the pupils.

Farm animals, T. F. Hunt and C. W. Burkett (New York and London, 1914, pp. 1X+534, pl. 1, figs. 469).—In preparing this book, which is intended for pupils between the ages of 14 and 18 years, the authors have sought to cover the whole field of animal industry. They have assumed that the subject matter will occupy 16 full weeks of three recitations each, and that two days each week would be devoted to practicums or one day to practicums and one to a review. Each lesson contains a note to the teacher and 15 paragraphs in which are developed the ideas or set of ideas discussed in the lesson text.

Horses (Cornell Rural School Leaflet, 8 (1914), No. 1, pp. 73-92, figs. 14).—Brief suggestions are given by Alice G. McCloskey and E. M. Tuttle on methods of teaching lessons on horses, followed by lessons by M. W. Harper on the characteristics and types of horses, estimating age, harness and harnessing, and training, and a score card.

How to teach a lesson on the dairy cow, G. A. BRICKER (Rural Educator, 4 (1914), No. 3, pp. 48, 49, figs. 4).—The author considers the fundamental differences in dairy cows for one recitation, and the breeding and selection of cows for certain purposes and the naming and locating of the principal parts of the cow's body for a second recitation. A cloth wall diagram of a dairy cow is illustrated.

Principles of bookkeeping and farm accounts, J. A. Bexell and F. G. Nichols (New York, Cincinnati, and Chicago, 1914, pp. 104).—This is a teacher's reference book to accompany the author's Principles of Bookkeeping and Farm Accounts, previously noted (E. S. R., 29, p. 792). It suggests methods of instruction and contains model entries of transactions illustrating principles taught in the various lessons.

The subject matter in home economics courses for high schools: Factors determining the choice of subject matter in a laboratory course in foods,

JESSAMINE C. WILLIAMS (Manual Training and Vocational Ed., 16 (1914), No. 2, pp. 74-81).—The subject matter of a laboratory course in foods is considered from the points of view of the pupil, her environment, and the school.

Home economics in village and rural schools, Frances L. Brown (Agr. Ed. [Kans. Agr. Col.], 6 (1914), No. 7, pp. 24, figs. 4).—The author discusses the importance of training for the home and plans for cooking, sewing, lunches, and girls' clubs in village and rural schools, including equipment.

Domestic economy in the schools (Bul. Univ. Texas, No. 326 (1914), pp. 69, pls. 4).—This bulletin, edited by the Texas Home Economics Association, contains suggested equipment and cost data for a domestic economy laboratory and domestic art room and syllabi of domestic economy for elementary and secondary schools of Texas. This is the first step of the association, organized in 1913, in its endeavor to place the course of study in domestic economy throughout the State on a uniform basis, raising the general standard of the work, and obtaining for it the same credit and recognition accorded to other subjects in the curriculum.

[A course designed for instruction in food and cookery], Helen M. Spring (*Philadelphia: Drexel Inst.*, 1914, eards 43).—Each of these cards covers a special phase of food or cookery. They are designed for laboratory use.

The busy housewife, Antonie Steimann (Die tüchtige Hausfrau. Stuttgart and Vicnna, 1913, vols. 1, pp. XVI+747, pls. 17, figs. 1443; 2, pp. VI+595, pls. 18, figs. 161, sup. pp. 7, pls. 6).—The first of these volumes has to do with household labor of different sorts, clothing and garment making, sewing, embroidery, needlework, and similar topics, a series of patterns being appended. The second has to do with food and its preparation, and has a supplement on The Pig and its Use as Food, containing a number of plates showing the method of cutting up pork, together with descriptive text.

[Home economics instruction], MARY E. FRAYSER (Winthrop Normal and Indus. Col. S. C. Bul., 7 (1913), No. 1, pts. 1, pp. 22; 2, pp. 44; 7 (1914), Nos. 3, pt. 2, pp. 36, figs. 9; 4, pt. 2, pp. 40, figs. 10).—These bulletins treat respectively of a plan for organizing and operating homekeepers' clubs in South Carolina, women's club programs in home economics, the care and feeding of children, and fireless cooking.

School gardens, R. P. Steeves (Dept. Agr. New Brunswick Bul. 1 [1914], pp. 7).—Suggestions for practical work in gardening during the fall term are given.

School and home gardening for use in primary grades ([Philippinc] Bur. Ed. Bul. 31, rev. (1913), pp. 115, figs. 75).—This bulletin outlines work in gardening for the elementary schools of the Philippine Islands, in which it is a required and accredited subject. The preparing, planting, care, and products of the school and home garden, school ground improvement, the teacher's home garden, the garden during vacation, etc., are discussed, and suggestions offered for classroom lessons.

The 1914 corn campaign ([Philippine] Bur. Ed. Circ. 46, s. (1914), pp. 24).—This is a revision of Circular 80, previously noted (E. S. R., 30, p. 395).

Arbor Day in California, 1914 (Sacramento: State Supt. Pub. Instr., 1914, pp. 24).—This contains nature poems and songs; articles on Arbor Day, by Theodore Roosevelt; Birds and Their Relation to Agriculture, by Mrs. Ethel Bloodgood, and California Trees; outlines for compositions, declamations, etc.; facts about birds and trees; program suggestions, etc.

Arbor Day observance, 1914, R. P. Steeves (Dept. Agr. New Brunswick Circ. 1 (1914), pp. 4).—Suggestions are offered to teachers and others to encourage the improvement of rural school grounds as an observance of Arbor Day.

Arbor Day (Hawaii Ed. Rev., 2 (1914), No. 8, pp. 12, 13).—This article gives directions for the treatment of plants when received from the nursery and planting shade and ornamental trees.

Knapp Agricultural Day program for celebration in the schools (Bul. Ceorge Peabody Col. for Teachers, n. ser., 2 (1913), No. 1, pp. 24, figs. 2).—The seasons for celebrating Knapp Agricultural Day and the establishment of the Seaman A. Knapp school and farm, the work to be undertaken by the school, and a suggested program for Knapp Agricultural Day are outlined, and hints and material for carrying out the program are suggested.

References for use in agricultural nature-study, G. H. Trafton (Mankato, Minn.: State Normal School, [1914], pp. 39).—This is a topical list of references to nature-study literature.

Agricultural extension in the high school, A. W. Nolan (III, Agr., 19 (1914), No. 3, pp. 230, 231, fig. 1).—The author calls attention to four distinct modes of approach to agricultural extension work that may be made in the high schools of Illinois offering agricultural courses, viz. the community survey, home-project work, individual work among farmers, and the organization of farmers' interests.

Edgar County country life clubs (Paris, Itl.: county Supt. Schools, [1914], ρ_{P} , 20).—Programs and suggestions for community meetings are presented.

Report of the women's institutes for the Province of New Brunswick. 1913 (*Rpt. Women's Insts. New Brunswick, 1913, pp. 174, fig. 1).*—This is the second annual report of the women's institutes in New Brunswick, including the proceedings of the annual convention held in 1914, together with addresses and statistical data on the number of institutes, and their membership, attendance, receipts, and expenditures.

MISCELLANEOUS.

Twenty-sixth Annual Report of Alabama College Station, 1913 (Alabama Col. Sta. Rpt. 1913, pp. 35).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1913, and reports of the director and heads of departments on the work and publications of the station during the year.

Annual report of the director for the fiscal year ending June 30, 1913 (Delarcare Sta. Bul. 103 (1914), pp. 16, fig. 1).—This contains the organization list and the report of the director on the work and publications of the station. It includes a financial statement for the fiscal year ended June 30, 1913.

The uses of the agricultural experiment station, E. H. Jenkins (Connecticut State Sta. Bul. Inform. 6 (1915), pp. 4).—The work of the station for individual farmers is explained and the conditions under which it may be done are briefly noted.

Program of work of the United States Department of Agriculture for the fiscal year 1915 (Washington: Govt., 1914, pp. 278).—The proposed activities of this Department are set forth in project form.

Federal legislation, regulations, and rulings affecting agricultural colleges and experiment stations (U. S. Dept. Agr., Office Expt. Stas., Federal Legislation (ctc.) Affecting Agl. Cols. and Expt. Stas. (1914), pp. 28).—A revision to July 1, 1914, of the circular previously noted (E. S. R., 25, p. 393).

NOTES.

Arizona University.—The legislature has accepted the provisions of the Smith-Lever Act and authorized the necessary appropriations. It also has empowered counties to appropriate not exceeding \$1,000 per annum for the payment of salaries and expenses of county farm advisors.

Kentucky Station.—L. R. Himmelberger, instructor in bacteriology in the Michigan College and assistant in the station, has been appointed assistant in the hog cholera serum production, beginning March 1.

Maryland College.—The short courses in agriculture and domestic science which closed March 13 were marked by increased attendance and interest over previous years. The new course in road making and maintenance attracted special attention in the State.

Missouri University and Station.—The resignations are noted of H. K. Thatcher, assistant in the soil survey, and B. Szymoniak as assistant in horticulture, the latter to become associated with the fruit and truck-crop demonstration work of the North Carolina College. B. L. France has been appointed farm advisor for St. Francis County and M. E. Hays assistant in horticulture.

Montana College and Station.—Appropriations have been made by the legislature for 1915–16 of \$85,000 for college maintenance, \$59,000 for station maintenance, \$5,500 for the dry farming substation, \$2,500 for the horticultural substation, \$1,000 for the Huntley substation, \$5,000 for the Northern Montana substation, \$4,000 for the grain laboratory, \$10,000 for farmers' institutes, and \$13,182 for agricultural extension. For the following year these grants are continued with increases of \$2,500 for the station, \$500 for the grain laboratory, and \$3,000 for extension work. In addition \$2,000 was granted the station as a revolving fund for the hog cholera serum work.

The annual farmer's week, January 25-30, is reported as the most successful yet attempted.

New Mexico College and Station.—The legislature has appropriated \$30,000 for college maintenance and \$5,000 for station work. The latter is the first appropriation ever made by the State for the maintenance of the station.

R. W. Latta, assistant in charge of dairying, was transferred March 1 to the extension division, being succeeded by J. R. Meeks of the animal husbandry department and he in turn by R. L. Stewart,

Oklahoma College and Station.—The faculty has decided to raise the entrance requirements to the full 15 unit credits. A 3-year secondary school course of a preparatory nature will be offered by the college until the high schools of the State can provide the necessary facilities. In conjunction with this secondary school course there will also be a 3-year course in practical agriculture designed to supply farm boys with a practical course of study without high school preparation and who desire to return immediately to the farm.

M. A. Beeson, president of the Meridian (Miss.) Male College, has been appointed professor of agronomy and agronomist, vice O. O. Churchill. J. M.

Fuller, who has been associate professor of dairying in the South Dakota College and dairy bacteriologist in the station has been appointed head of the dairy department beginning April 1. C. A. Burns has been appointed assistant in dairying, and W. L. Blizzard and D. A. Spencer assistants in animal husbandry.

Texas Station.—The governing board of the State substations has been reconstituted as follows: P. L. Downs of Temple, president: Charles Rogan, of Austin, vice-president: J. E. Boog-Scott, of Coleman; and W. P. Hobby, of Beaumont. H. C. Stewart resigned March 1 as superintendent of the Pecos substation and has been succeeded as acting superintendent by J. W. Jackson, assistant superintendent of the Troupe substation.

Utah College and Station.—Dr. L. D. Batchelor, professor of horticulture and horticulturist since 1911, has been appointed associate professor of plant breeding in the Graduate School of Tropical Agriculture and associate in plant breeding work at the citrus substation at Riverside, Cal., and will also be engaged in extension work. The appointment took effect March 1.

West Virginia Station.—At the recent session of the legislature, \$20,000 per annum was appropriated for the current expenses of the station and \$35,000 and \$40,000 for the first and second years for agricultural extension work. An act was passed accepting the provisions of the Smith-Lever Act, and another act authorizing county courts to pay part of the salary of county agricultural agents, including women workers, whenever a county agricultural organization of not less than fifty members will guarantee their expenses.

Paul B. Bennetch, associate professor of dairy husbandry and dairyman at the station, resigned January 1, and the dairy husbandry work has been combined with the department of animal husbandry. G. L. Thompson, a recent graduate of the Iowa College, has been appointed instructor in dairy husbandry.

Wyoming University and Station.—Ex-governor Joseph M. Carey and Mrs. B. B. Brooks have been appointed to the board of trustees, the former vice Gibson Clark, deceased. S. M. Fuller, assistant in the wool department, has been appointed county agent for Sheridan County, beginning March 15, vice H. E. McCartney, who is to become secretary of the Horse Breeder's Association of Indiana.

Second Pan-American Scientific Congress.—Preliminary programs have been issued by the State Department for this congress, which will hold its next session in Washington, D. C., from December 27, 1915, to January 8, 1916. Appropriations aggregating \$50,000 have been made by the United States for the congress, and William Phillips, Third Assistant Secretary of State, is chairman of the executive committee which is charged with its organization and procedure. George M. Rommel, of the Bureau of Animal Industry, is the representative of this Department on the executive committee.

The congress will be organized into nine sections. Workers in agricultural science will be especially interested in Section 3, conservation of natural resources, agriculture, irrigation, and forestry, which will be devoted to a consideration of the conservation of (a) mineral resources, (b) forests, (c) water for power, (d) animal industry, and (e) plant industry, and to discussions of the agricultural phases of irrigation and the marketing and distribution of agricultural products. Section 2, astronomy, meteorology, and seismology, is to include discussions of agricultural meteorology; Section 4, education, problems of agricultural education and research: Section 5, engineering, the engineering features of irrigation and drainage; Section 7, mining and metallurgy, economic geology and applied chemistry, papers on fertilizers and other agricultural chemical industries; and Section 8, public health and medical science, papers on nutritional diseases, food supply, etc.

NOTES. 499

Membership in the congress is open to official delegates of the countries represented, representatives of the universities, institutes, societies, and scientific bodies of these countries, and others who may be invited by the executive committee. Americans prominent in the field of science may also be appointed honorary members by the executive committee.

The official languages of the congress will be English, Spanish, Portuguese, and French. All papers should be received by October 1 and should be accompanied by résumés of not over 1,500 words followed by a footnote giving a bibliography of the subject. It is suggested that papers have special reference to the trend of recent progress and probable development in the immediate future.

Federal Agricultural Legislation .- Practically all the agricultural legislation to be completed at the closing session of the Sixty-third Congress was embodied in the agricultural and other appropriation acts, discussed editorially in this issue. A standard barrel was prescribed for fruits, vegetables, and other dry commodities. For commodities other than cranberries, this standard barrel must contain 7,056 cubic inches, while that for cranberries must have staves 28.5 inches in length and not greater than 0.4 inch in thickness, a diameter of head of 16.25 inches, a distance between heads of 25.25 inches, and a circumference of bulge of 58.5 inches, outside measurement. Sales of these commodities, except by weight or measure, in barrels of smaller capacity than these standards or subdivisions known as thirds, halves, or three-fourths barrels are prohibited under penalty of a fine not exceeding \$500 or imprisonment not exceeding 6 months, except that foreign shipments may be made which comply with the laws of the importing country. Reasonable variations are permitted under regulations to be established by the Department of Commerce. The act becomes effective July 1, 1916.

Under another act, one section of each township in the Tanana Valley. Alaska, is, with certain exceptions, reserved for the support of a territorial agricultural college and school of mines. A tract of four sections near Fairbanks is, aside from existing claims, granted to the Territory as a site for this institution. A portion of this tract is now occupied by the Fairbanks substation, and the act provides that it may continue to be used for that purpose until otherwise ordered by the President or Congress.

Agriculture and Domestic Science in Missouri High Schools.—According to a study recently made by W. J. Bray, professor of chemistry at the State Normal School, Kirksville, Mo., agriculture is the only recognized high school science that shows any gain in its percentage of enrollment for the 9 years from 1905 to 1914, viz, 300 per cent, while the enrollment in science as a whole, excluding domestic science, has declined from 64.4 to 49.2 per cent. Domestic science, though not taught as a science, has increased its enrollment from 9.3 per cent in 1906, when it was introduced into the high schools of Missouri, to 13.3 per cent in 1914. It is concluded that science is not holding its own because, as taught, it is failing to meet the popular demand for a practical usable education, and that there is no room in the secondary school for science for science sake.

Agriculture in Tennessee High Schools.—To adapt county high schools to the operations of the Smith-Lever act, an experiment is being made in the new Tennessee high school course of study in dividing the year into three terms of 12 weeks each instead of two terms of 18 weeks each. The demonstrators in agriculture and home economics are to spend the fall and spring terms in the field and the winter term in the high schools. Plans are being made for short courses for adults during these winter terms at several of the high schools,

notably at Farragut and Benton. The agricultural work will be begun at once but the home economics work will be delayed until next year in order that plans can be more carefully matured.

Government Aid to Agriculture in Greek Macedonia.-During 1914 the Ministry of National Economy of Greece expended more than \$16,000 for repairing and equipping the model farm of Saloniki, which is to be designated the principal agricultural school in New Greece. This school, which was established 20 years ago under the Turkish regimé, has three buildings for scholastic purposes (one of which contains a museum and also a chemical laboratory), a station for breeding purposes, etc. The Greek government expects to complete the construction of a large new school building which was started before the Balkan wars. The farm is devoted to the growing of cotton, tobacco, sesame, sorghum, barley, oats, beets, and other plants and vegetables, and there is also a modern dairy and cheese house. Modern agricultural machinery and chemical fertilizers are used, and a nursery with about 100,000 trees of various kinds, including a large number of fruit trees, is expected to be of service in replanting the deforested sections of Macedonia. Improved methods of silk culture have given very satisfactory results during the past year. A farm viticulturist visits the various villages to give advice to vine growers.

Agricultural Instruction in Ceylon.—In 1913 there were in Ceylon 282 government school gardens and 47 aided schools registered for the grants payable by the education department, viz, \$16.22 for a garden of an acre or more and \$9.73 for one not less than one-third of an acre in extent; 8.288 packets of seed and 4.496 plants were distributed to school gardens, seeds were tested for the agricultural society, and 4 hives of bees were stocked and supplied to applicants. A prize fund of \$811 was available, half the sum awarded to each garden being divided among five students showing the best work in both school and home gardening. A junior agricultural reader was prepared by the superintendent of school gardens, and a senior reader was in course of preparation. A circular containing instructions on the planting of school gardens was issued to teachers. Two assistant teachers of government vernacular schools and three probationary agricultural instructors were given training at the stock garden. A central agricultural school is to be established at Peradeniya.

Miscellaneous.—The death in the European War is reported of the Prussian Conservator of Forests, Professor Karl Fricke, director of the Forest Academy of München.

The King of England has given permission for the use of a portion of the royal estate by the school of forestry of Cambridge University, for purposes of experimentation and demonstration.

A convention was held in Chicago, February 12 and 13, of representatives of six of the agricultural magazines published by the agricultural colleges. Considerable progress is reported in the standardization of the size of publication, number of issues, advertising rates, etc.

A gift by Theodore N. Vail has been accepted by the Vermont legislature of the agricultural school at Lyndon and other land and equipment. The gift is estimated at about \$150,000.

The next annual meeting of the American Association of Farmers' Institute Workers has been fixed for August 13 and 14 at the University of California.

The new agricultural buildings of Oxford University, costing about \$30,000, have recently been occupied.

EXPERIMENT STATION RECORD.

Vol. XXXII

Abstract Number.

No. 6.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL CHEMISTRY-AGROTECHNY.

Chemistry of agriculture, C. W. Stoddart (Philadelphia: Lea and Febiger, 1915, pp. VI+364, pl. 1, figs. 83).—This book on general agricultural chemistry is intended as a brief treatise, particularly for students, but sufficiently elementary for general reference. The contents are as follows: The plant: Germination of the seed, growth of the plant, plant compounds, and crops; factors in plant growth: The air, the soil-organic matter, the soil-inorganic matter, fertilizers, lime, farm manure, soil and fertilizer analysis, insecticides and fungicides, and the gas engine; the animal: The chemistry of animal physiology, food and digestion, and milk and dairy products.

The farmer as a manufacturer, A. T. Stuart (Canada Expt. Farms Bul. 20 (1914), 2. ser., pp. 16).—An outline in popular language of some basic principles in agricultural chemistry. That the farmer is the world's real manufacturer of proteins, fats, carbohydrates, and fiber for making clothes is pointed out. The object of the bulletin is to present in a similar manner some illustrations of the chemical processes which take place in vegetable and animal life and to show how the farmer, through the agency of his crops and stock, uses the raw materials supplied by nature for the manufacture of his finished products.

Dairy chemistry: A practical handbook for dairy chemists and others having control of dairies, H. D. RICHMOND (London: C. Griffin & Co., Ltd., 1914, 2. rev. cd., pp. XI+434, figs. 49).—The second edition of this work, the first of which was issued in 1907. It is stated that the obsolete portions of the text have been eliminated and replaced by more recent matter.

Analytical chemistry.—I, Qualitative analysis, II, Quantitative analysis, F. P. Treadwell (Analytische Chemic. Leipsie: F. Deuticke, I, Qualitative Analyse, 1914, 8. ed. rev. and enl., pp. XII+5.2.2, pls. 3, figs. 25; II, Quantitative Analyse, 1913, 6. ed. rev. and enl., pp. IX+734, pl. 1, figs. 28).—Revised and enlarged editions of this well-known work.

The germplasm as a stereochemic system, E. T. REICHERT (Sci. Amer. Sup., 78 (1914), Nos. 2023, pp. 226, 227; 2024, pp. 242, 243).—The thesis of this paper is that every individual is a chemical entity that differs in characteristic particulars from every other. The subject is discussed in the light of the author's researches, previously noted (E. S. R., 31, p. 804).

The constituents of the leaves and stems of Daviesia latifolia, F. B. Power and A. H. Salway (Jour. Chem. Soc. [London], 105 (1914), No. 617, pp. 767-778).—"The material employed for this investigation consisted of the leaves and stems of D. latifolia (natural order Leguminose), which had been specially

collected for the purpose in Victoria, Australia. An alcoholic extract of the material, when distilled with steam, yielded a small amount of a pale yellow essential oil, which possessed a pleasant, aromatic odor, and gradually deposited some crystals of benzoic acid.

"From the portion of the alcoholic extract which was soluble in water the following definite compounds were isolated: (1) Benzoic, salicylic, p-coumaric, and fumaric acids; (2) a crystalline benzoyl derivative of a new disaccharid (glucoxylose), which possesses an extremely bitter taste. This bitter substance has the empirical formula $C_{25}H_{25}O_{12}H_{2}O$, melts at 147 to 148°, and has been designated dibenzoylglucoxylose; (3) a quercetin glucosid, $C_{27}H_{26}O_{16}$, which is probably identical with rutin. The aqueous liquid contained, furthermore, a quantity of sugar, which yielded d-phenylglucosazone (melting point 210°).

"The portion of the alcoholic extract which was insoluble in water, consisting chiefly of resinous material, amounted to about 8.6 per cent of the weight of the drug. From the resinous material there were isolated: (1) Myricyl alcohol, C₃₀H₂₀O; (2) hentriacontane, C₃₁H₄₃; (3) a phytosterol, C₂₁H₄₀O; (4) a mixture of fatty acids, consisting of palmitic, stearic, and linoleic acids. The resin also contained a considerable proportion of the above-mentioned dibenzoylglucoxylose, together with free benzoic acid.

"This investigation has shown that the bitterness of the leaves of *D. latifolia* is due to the crystalline substance which has been designated dibenzoylglucoxylose. The latter represents a type of compound which has not hitherto been observed to occur in nature, and its characters will be fully described in a subsequent communication."

The nitrogenous constituents of hops, A. C. Chapman (Jour, Chem. Soc. [London], 105 (1914). No. 621, pp. 1895–1907).—A detailed study of the various nitrogenous constituents present in hops, made for the purpose of noting especially those substances which might be of help in solving some of the vexed questions as to the therapeutic effects of various kinds of beers, and also as to whether the nitrogenous substances would have some effect on the vitality of the yeast organism. In some cases the hops were extracted in the laboratory and in others the extract prepared by a commercial concern was used.

The investigation was confined especially to those substances soluble in boiling water. From the aqueous solution histidin, arginin (?), betain, cholin, asparagin, adenin, hypoxanthin, a small amount of a definitely alkaloidal substance, a colored nitrogenous substance which was acid in character and soluble in alkali and forming a brownish-red solution, and substances exhibiting properties of complex amino acids or polypeptids, or mixtures of the same, were isolated. A crystalline substance melting at about 70° C., which was a nonnitrogenous compound and almost insoluble in alcohol, was also noted. Potassium nitrate was obtained from an alcoholic extract of hops.

The carbohydrate matter was also investigated and will be reported upon in a later communication. No alkaloids giving reactions similar to morphin were noted except with one method and then only a trace.

An investigation of the diastase of alfalfa and the effect of rapid curing upon the food value of alfalfa, R. C. Shuey (Jour. Indus. and Engin. Chem., 6 (1914), No. 11, pp. 910-919, fig. 1).—The fact that diastase has been demonstrated in a large number of plants and in various parts of plants indicated the probability of the diastatic content of fodders bearing an important relation to the availability of the food constituents. "Experiments were conducted along similar lines, using alfalfa as an example of a highly diastatic plant, and endeavoring to learn the optimum conditions for the production and retention of diastase in a cured hay."

"The diastatic activity of alfalfa is greater in the morning or after a period of darkness than after a period of exposure to light. There is much more diastase present in the plant during the warm, active, growth-producing summer than during the spring or fall. Young plants contain more diastase than older ones. Drying at elevated temperatures in a humid atmosphere decreases the diastatic activity, even though the temperature is only 50° F. Drying in a current of air with gradually increasing temperature, on the other hand, increases the activity markedly. Light and weathering in the field tend to destroy the diastase. Rain during curing is very detrimental. Highly diastatic alfalfas generally show a greater solubility in water by autodigestion than samples low in diastase. However, the degree of solubility in water can not be increased above a certain limit. The loss in digestible constituents during handling and curing in the field may vary from 20 per cent under favorable conditions to as much as 50 per cent under adverse weather conditions.

"Curing by artificial heat, using the principle of countercurrents, gives a hay of better color, odor, and flavor than can be produced by other means. The hay appears to retain many of the valuable properties of the green plant, which are ordinarily lost in curing. The cost of artificial drying is estimated to be less than the losses generally sustained in field curing and, therefore, it ought to be possible to conduct drying at a profit when the drier can be located near both field and source of fuel."

Concerning the presence of diastase in certain red algo, E. T. Bartholomew (Bot. Gaz., 57 (1914), No. 2, pp. 136-147).—"There is present in the red algor a diastase which will digest the starch of higher plants. The manner of action of this enzym indicates that it is at least partially composed of a translocation diastase. The diastase of the red algor, like that of the higher plants, is probably not composed of a single enzym, but of a series of amylases and dextrinases. Judging by the action of the algal extract upon cornstarch, the diastase is a rather slow-working enzym.

"The series of digestion processes resulting from the application of the algal diastase to cornstarch would indicate that the subtance composing the grains of the red algæ is very similar to that of the starch grains of higher plants."

The survival of amylase in dried fodders, R. E. Neidig (Jour, Amer. Chem. Soc., 36 (1914). No. 6, pp. 1312-1314).—The amylolytic activity of five dried fodders about six months old, viz, two alfalfa hays, clover hay, timothy hay, and corn stover, was calculated on the basis of 100 gm. of dry fodder, the method of Sherman et al. (E. S. R., 24, p. 122) being used for determining the amylolytic activity. "The addition of sodium phosphate and sodium chlorid as electrolytes failed to increase the activity, probably because electrolytes were abundantly present in the crude enzym preparations."

The influence of the fat content of milk upon the rate of coagulation by rennet, A. Kreidl and E. Lenk (Biochem. Ztschr., 63 (1914), No. 2-3, pp. 151-155, figs. 3).—Despite the fact that investigations have been made under uniform conditions the coagulation time of milk by rennet was not found to be constant. The rate is dependent upon the fat content of the milk, the time required for coagulation increasing with the fat content. The work was done with skim milk, whole milk, ordinary cream, and whipped cream.

A contribution to the biochemistry of cheese ripening.—I, About the occurrence of p-oxyphenylethylamin in normal cheese and its formation by lactic acid bacteria, F. Ehrlich and F. Lange (Biochem. Ztschr., 63 (1914), No. 2-3, pp. 156-169).—Lactic acid bacteria are said to form p-oxyphenylethylamin from amino acids, i. e., tyrosin by the scission of carbon dioxid from the

same. Appreciable amounts of this substance were noted in normal Swiss and Emmental cheese, especially in the latter. See also previous notes (E. S. R., 14, p. 4115; 21, p. 478).

An organism similar to those belonging to the *Bacillus casei* group was isolated from Swiss cheese. The indications were that oxyphenyl lactic acid was present in both cheeses but no tyrosol could be noted.

The gravimetric determination of calcium as calcium oxalate, S. Goy (Chem. Z1g., 37 (1913), No. 131, pp. 1337, 1338).—For the determination of calcium in foods, soils, plant ashes, etc., the methods in vogue are tedious and time-consuming. In most cases the calcium is determined as oxid or carbonate. Attempts to weigh the calcium oxalate precipitate directly after drying resulted in showing the feasibility of the procedure providing the drying was done in the Gooch crucible. The precipitate when dried at from 100 to 105° C, was found to contain one molecule of water of crystallization which will not volatilize by continued drying at the above-named temperatures. By drying at 130°, the temperature used in the perchlorate method, a loss in weight is experienced and the salt goes over into the anhydrous condition.

Study of methods used in alkali determinations, A. E. Vinson and C. N. Catlin (Arizona Sta. Rpt. 1913, pp. 274–277).—This is a comparative study of the methods for alkali determinations in soil, which was prompted by the fact that some investigators were reporting results for black alkali far in excess of the limit usually acceptable as that of tolerance by most economic crops in the presence of very large amounts of gypsum, a result which could not be obtained by methods in use at other stations.

The soils used in comparing the methods were a strongly black alkaline soil from the University of Arizona farm, a moderately black alkaline soil from Santa Cruz Valley, and a gypsum soil from Santa Cruz Valley, and the methods studied were the California, Montana, Bureau of Soils. Texas, New Mexico, Utah, and Arizona. The determinations made were total solids, chlorids as sodium chlorid, and alkalinity expressed in terms of sodium carbonate. The comparisons show that the Arizona method gives high results in all determinations except the chlorids. This is especially true for black alkali, and it was found that it requires a fairly large proportion of water to soil and long digestion to reach a maximum extraction of total solids. Direct titration of the soil filtrate with methyl orange as the indicator may show black alkali in a strongly gypsum soil and the percentage would increase with the carbon dioxid in the water used in making the solution.

Colorimetric estimation of iron in water, F. Gothe (Ztschr. Untersuch. Nahr. u. Genussmtl., 27 (1914), No. 9, pp. 676-683; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, 11, pp. 581, 582).—It is claimed that the colorimetric method of determining iron by means of potassium thiocyanate is liable to yield low results when ferrous salts are present in a water in which the iron has been insufficiently oxidized by treatment with hydrochloric acid and potassium chlorate. The error is due to the influence of the hydrochloric acid on the ferric thiocyanate and to a certain extent on the quantity of thiocyanate added. More satisfactory results can be obtained by oxidation with nitric acid.

The following procedure is recommended: "One hundred cc. of the water is acidified with 1 cc. of hydrochloric acid (specific gravity 1.125), a few crystals of potassium chlorate are added, and the mixture is evaporated to dryness. The residue is treated with 1 cc. of hydrochloric acid (specific gravity 1.125) dissolved in distilled water, diluted to 95 cc., and 5 cc. of 10 per cent potassium thiocyanate added. The coloration is compared with that produced by a known quantity of iron under similar conditions,"

A simple, exact, and reliable method for the quantitative determination of lead in drinking water, C. Reese and J. Drost (Gsndhts, Ingen., 37 (1914), No. 8, pp. 129-133).—After discussing the faults of the various methods hither to proposed for estimating the amount of lead in water, a colorimetric method is suggested. It consists essentially in noting the color produced in a volume of water (previously evaporated with concentrated hydrochloric acid and again made up to volume with distilled water) with hydrogen sulphid. A comparison is made with tubes containing a known amount of acetic acid solution, lead nitrate of known strength, and hydrogen sulphid.

Estimation of iodin, especially in organic substances, R. GRÜTZNER (Chem. Ztg., 38 (1914), No. 72, pp. 769, 770; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, II, pp. 573, 574).—A known quantity of the substance is mixed with powdered sodium hydroxid, moistened and dried, sodium or barium peroxid is added, and the mixture is incinerated. After cooling, a small quantity of charcoal is added and the mixture is heated again. The fused mass which results is then dissolved in water and filtered. If barium peroxid is used the solution can be treated with carbon dioxid and sodium sulphate before filtration. The resulting alkaline solution is boiled after the addition of a little crystalline potassium permanganate and talcum, acidified with sulphuric acid. boiled, rendered alkaline, and boiled again after adding alcohol. The mixture is filtered while hot, the excess of alcohol being expelled by boiling the filtrate, which is then rendered slightly acid with a mixture consisting of sulphuric and phosphoric acids. Ammonium sulphate is added, the mixture boiled for three minutes, cooled, and the iodic acid titrated after the addition of sulphuric acid and potassium iodid. Six atoms of iodin are thus liberated and when titrated they correspond to one atom of iodin in the original substance.

Colorimetric estimation of creatin, E. BAUR and G. TRÜMPLER (Zlsehr, Untersuch, Nahr, u. Genussmil., 27 (1914), No. 10, pp. 697-713, figs. 3; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, II, p. 595).—An investigation of Jaffe's method for the estimation of creatin as regards the influence of time, temperature, and concentration of acid on the conversion of creatin into creatinin.

It was found that in the case of meat extracts the creatin is converted completely when 10 gm, of the extract is heated with 100 cc, of normal hydrochloric acid for four hours at 97° C. The estimation of creatin in meat extracts Is carried out as follows:

"Ten gm. of the extract is dissolved in water to give 100 cc. of solution; 5 cc. of this solution is then treated with 15 cc. of saturated pieric acid solution and 5 cc. of 10 per cent sodium hydroxid solution. After seven minutes the mixture is diluted to 500 cc., and the coloration compared with that exhibited by a definite depth of twice-normal potassium dichromate solution. The result gives the quantity of pre-formed creatinin. A second portion of 10 gm. of the sample is then heated with hydrochloric acid as described above; after cooling, 5 cc. of the solution is neutralized, treated with pieric acid and sodium hydroxid, diluted to 500 cc., and the coloration compared. The amount of creatin plus creatinin is thus obtained. The comparisons should be made while the solutions are at a temperature of 17°. Liebig's meat extract was found to contain from 3.72 to 9.76 per cent of creatinin and from 2.09 to 5.58 per cent of creatin. Meat extracts prepared by the authors (1 kg. of flesh yielded 30 to 35 gm. of extract) contained from 7.5 to 8.9 per cent of creatin plus creatinin."

Flours, starches, bread, alimentary pastes, and pastry, M. Arpin (Farines Fécules et Amidons, Pain, Pates Alimentaires, Patisseries. Paris: C. Béranger, 1913, XIII+190, pls. 8, figs. 9).—The book includes methods of analysis of these substances, the interpretation of the analyses, and legislation in regard to

these products. The various sources of flour are considered and photomicrographs are included.

The rapid determination of boric acid normally present in foods, or extraneous boric acid, G. Bertrand and H. Agulinon (Ann. Falsif., 7 (1914), No. 65, pp. 119-121).—With a colorimetric method devised by the authors it is possible to estimate quantitatively and easily small amounts of boric acid in foods with sufficient accuracy to determine whether the boric acid was present normally or had been added as a preservative. This is demonstrated by giving the results of an examination of a large variety of substances, including fruits, vegetables, cereals, meats, eggs, and milk.

Detection of formaldehyde in foods, F. RACHEL (Pharm. Zentralhalle, 54 (1913), No. 31, pp. 759-761; abs. in Jour. Chem. Soc. [London], 104 (1913), No. 612, 11, p. 891).—Utilizing the suggestion made by Friese, the following process for the detection of formaldehyde in meat, caviar, and fish is recommended;

Acidify the substance with phosphoric acid, heat in a current of steam, and mix 1 to 2 cc. of distillate with 4 cc. of milk free from formaldehyde and 10 cc. of hydrochloric acid (sp. gr. 1.19) to which has been added 1 drop of nitric acid per 300 cc. When formaldehyde is present a bluish-violet coloration appears. Colors appearing after five minutes are taken as a negative result. When much formaldehyde is present milk does not give the reaction and the experiment must be repeated with pure water.

Detection and estimation of formic acid, H. FINCKE (Biochem. Ztschr., 51 (1913), No. 4, pp. 253-287, figs. 2).—The first part of this paper deals with the occurrence of formic acid, and the second with the reactions which were found useful in its qualitative and quantitative determination. Some of the quantitative methods are given with much detail.

The detection of formaldehyde in plants, H. Fincke (Biochem. Ztschr., 52 (1913), No. 3-4, pp. 214-225; abs. in Jour. Chem. Soc. [London], 104 (1913), No. 610, I, p. 947).—"For these researches [see also above] the Grosse-Bohle reagent for the detection of formaldehyde was employed. This consists of a rosanilin salt in the presence of sulphites and free hydrochloric acid, and is to be distinguished from the ordinary magenta-sulphite solution for detection of aldehydes, by the presence of free mineral acid. It was found by the author to be capable of detecting formaldehyde in the dilution 1:500,000, giving with the aldehyde a violet color. In numerous experiments on plants no indication of the presence of formaldehyde was obtained with the use of this reagent; furthermore, formaldehyde could not be detected by the reagent after addition to certain living plants.

"The author draws the conclusion that his investigations throw no light on the correctness or otherwise of Bayer's assimilation hypothesis."

About the detection of small amounts of formaldehyde and some formal-dehyde compounds with fuchsin-sulphurous-hydrochloric acid, H. FINCKE (Ztschr. Untersuch. Nahr. u. Genussmtl., 27 (1914), No. 1-3, pp. 246-253).— As formaldehyde is decomposed under certain conditions it is essential to know to what extent it occurred in foods. After repeating some of the work noted above, the author lays stress upon the fact that the fuchsin-sulphurous-hydrochloric acid test is less influenced by other substances than any of the other reagents used for detecting formaldehyde and consequently should find a wider field of application. The reaction differentiates itself from the usual aldehyde test by the fact that it is conducted in a medium containing an excess of free acid.

Attempts to substitute for rosolic acid similar coloring matters (highly methylated fuchsin, acid fuchsin, and acid violet) were unsuccessful. The fuchsin homologues, parafuchsin (C_{10}), fuchsin (C_{20}), fuchsin (C_{21}), and new fuchsin

(C_{22}), were compared, and all of these were decolorized by sodium sulphite with the exception of parafuchsin and the new fuchsin, which were only partly decolorized. The color of none of the dyes was affected by the addition of acid. Fuchsin (C_{20}) is the preferred reagent.

Formaldehyde is tested for directly in the distillate from the food and especially in the first runnings, providing that it is not in a fixed state. In milk or colorless substances the reaction can be made without previous distillation. Strongly colored solutions, such as wines and fruit jams, must first be decolorized with animal charcoal. The diminution of formaldehyde in food is said to be due either to fixation or to decomposition by micro-organisms. The extent of formaldehyde fixation is shown by the fact that rhubarb leaves having an addition of 1:10,000 when heated for an hour at 100° C. give no reaction for the substance.

Formaldeliyde may be converted into hexamethylentetramin and methylal. Urine and urea fix formaldeliyde very easily while milk fixes it only slightly. As hexamethylentetramin reacts only slightly at the beginning with fuchsin-sulphurous-hydrochloric acid, it is advisable to heat 10 parts of the solution with from 1 to 2 parts of hydrochloric acid on a water bath.

The detection of formaldehyde-sulphurous acid is also considered.

About the utility of vacuum distilling methods for detecting formic acid, T. Merl (Ztschr. Untersuch. Nahr. u. Genussmil., 27 (1914), No. 10, pp. 733-743).—This work deals especially with the separation of formic acid from acid sugar-containing fluids. It indicates that it is possible, by observing the specifications set down by Fincke (see above), to obtain the formic acid from such fluids without the formation of acid during the distillation process under diminished pressure. The apparatus employed was Anschütz and Reitter's.

The preliminary work was done with solutions of formic acid; formic and tartaric acid; formic acid and saccharose; formic acid, glucose, and tartaric acid; levulose; levulose and tartaric acid; invert sugar and saccharose; saccharose and tartaric acid; saccharose and phosphoric acid; and saccharose, phosphoric acid, and tartaric acid. Although very small amounts of formic acid were found in the case of sugar solutions containing tartaric, phosphoric, or no acids, with the ordinary vacuum distillation process it usually originated from impurities present in the sugar. The steam vacuum method has a greater tendency to form formic acid than the other methods.

Tests were also made with authentic samples of honey which had been analyzed previously by Fincke's procedure. Distillates from the head, thorax, and abdomen of bees (Apis mellifera) showed formic acid to be present in traces. A few distillation tests with benzoic, salicylic, and cinnamic acids led the author to conclude that the steam distillation method is preferable to the shaking-out method in the detection of preservatives.

Determination of formic acid in ketchup, C. A. Peters and L. P. Howard (Jour. Indus. and Engin. Chem., 7 (1915), No. 1, pp. 35-37).—This gives the details of a study made for the purpose of adapting the Fincke method (E. S. R., 26, p. 312), to the determination of formic acid in ketchup with the apparatus described. From 91 to 92 per cent of the total formic acid added to ketchup may be recovered in one and a half hours providing about 1,000 cc. of distillate is passed over.

The unsaponifiability of mowrah fat and its significance for the detection of mowrah fat in edible animal and plant fats, P. Berg and J. Angerhausen (Ztschr. Untersuch. Nahr. u. Genussmil., 27 (1914), No. 10, pp. 723-731).—
Mowrah fat is one of the raw materials used in the margarin industry. It has the consistency of American lard, and since its quality has been improved it is

considered a better substitute for animal fat than coconut or palm fat. The fat when liquetied by heat and allowed to cool at room temperature solidifies only partly. The fully solidified fat, like palm and coconut fats, shows in its surface and bottom a cellular and hoveycomb-like appearance. Its color is white with a greenish hue and only when heated is an odor perceptible. It has a nutlike taste with a slight oily-soapy flavor.

The physical and chemical properties are as follows: Polarization (20 gm. of fat in chloroform to make 50 cc. in all) in a 200 mm. tube+0.9 circular degree which corresponds to a specific rotation (100 gm. fat in 100 cc. polarized in a 100 mm. tube) of +1.12; refraction at 40° C., 51.9 to 52.2; saponification number, 193.6 to 194; iodin number, 60.4 to 60.8; Reichert-Meissl number, 1.43 to 1.65; and Polenske (new butter) number, 0.4.

No coloration was obtained with the Baudouin, Halphen, or Bellier test. The Soltsien reaction was negative. The unsuponifiable material of this fat possesses many characteristics not present in other plant fats, especially the presence of an optically active substance. It was separated into an optically active $[a]_D + 34$ substance, soluble in alcohol, and an inactive substance insoluble in alcohol.

Phytosterol could not be detected by either the Bömer or digitonin methods. This was due to the fact that mowrah fat contains only a very small amount of phytosterol. The unsaponifiable material present in mowrah fat, especially the alcohol-soluble optically active substance, is recommended as a basis for its detection in lard.

The detection of coconut oil in butter by the Polenske distillation method and the phytosterol acetate test of Bömer, C. Barthel and K. Sondén (Ztschr. Untersuch. Nahr. u. Genussmil., 27 (1914). No. 6, pp. 439-453, figs. 2).—For detecting added coconut fat in butter three tests can be employed, viz. the Polenske number, the phytosterol acetate method (E. S. R., 16, p. 18), and the refractometric reading. While the presence of coconut oil in butter will lower the refractometric index of the mixture it sometimes occurs that such mixtures may still have a higher reading than some pure butters, and this makes it necessary to supplement the refractometric test by another. On the other hand, the Polenske figure of butter is increased by the addition of coconut fat. In some cases an addition of 5 per cent of coconut fat may be detected by this method, and 10 per cent can be detected with certainty.

Butter obtained from cows fed on turnip leaves, coconut cake, peas, vetch, or horse beans, when examined by the Polenske method gave figures indicating the presence of an adulterant. When this is found to be the case the Bömer phytosterol acetate test, which is not so easy to conduct as the other methods, will have to be resorted to, and when vegetable fats are present in butter the melting point of the acetate obtained will be higher. With it the presence of added coconut fat in an amount of 10 per cent or over can be proved without difficulty.

Before testing for coconut fat in butter, Baudouin's test for sesame oil should be made, as all Swedish margarins must contain an addition of seasame oil.

The estimation of the water and fat content of butter with a new apparatus, R. Jungkunz (Chem. Ztg., 38 (1914). No. 9, p. 91. fig. 1).—A description of the apparatus and the results obtained with it. The results are compared with those given by the ordinary drying method in nickel dishes with and without pumice.

A simplified and inexpensive oxidase apparatus, H. H. Bunzel (*Jour. Biol. Chem.*, 17 (1914), No. 3, pp. 409-411, fig. 1).—A simplification of the apparatus previously described (E. S. R., 27, p. 9). The apparatus described previously

has not found its way into general use in plant physiological laboratories on account of its great cost.

"In addition to its simplicity and increased sensitiveness, the apparatus is much less fragile and very much easier to clean than the old one. As its only drawback must be mentioned the fact that there is no provision made for absorption of the earbon dioxid produced. Until the carbon dioxid production in the oxidation of the various oxidase reagents has been determined, the apparatus will furnish only comparative results."

See also other notes (E. S. R., 28, p. 314; 29, p. 550).

A proposed new standard loop for use in bacteriological tests of disinfectants, A. D. St. John (Jour. Indus. and Engin. Chem., 6 (1914), No. 11, p. 940, fig. 1).—A description of a cube-shaped loop devised for the purpose of eliminating some of the errors and difficulties encountered in the present methods of determining the antiseptic power of disinfectants.

Home canning, F. E. Miller (Virginia Truck Sta. Bul. 12 (1914), pp. 279-297, figs. 5).—This deals with methods of canning, especially those practiced in the home canning plant of the Virginia Truck Station. The bulletin is well illustrated, and gives explicit directions for canning, especially vegetables. A list of canning terms, with definitions thereof, is also given.

Fruit preserving: Canning, bottling, jam making, and candying peel, W. J. Allen (Dept. Agr. N. S. Wales, Farmers' Bul. 88 (1914), pp. 26, figs. 21).—This pamphlet contains directions for earrying out this work in the home and on a small scale. The outfits required for both canning and bottling are described in full and illustrated. Hints are also given on the selection and preparation of the fruit.

Manufacture of textile fibers from Epilobium angustifolium, K. Schumann (German Patent 269,350, Jan. 6, 1912; abs. in Chem. Ztg., 38 (1914), No. 14, Repect., p. 66).—By proper fertilization of this plant a higher growth and better elasticity of the seed hairs are obtained. The seed hairs are then made rough with steam and spun.

METEOROLOGY.

Suggested changes and extension of the United States Weather Bureau service in California, G. S. BINCKLEY and C. H. LEE (Proc. Amer. Soc. Civ. Engin., 41 (1915), No. 2, pp. 249-258, fig. 1).—It is pointed out that the present weather service in California is not adequate for gathering the mountain climatic data necessary to furnish a basis for the forecast of future stream-flow variation. It is, therefore, suggested that more and better equipped stations be established in the most productive mountain drainage areas, under men especially fitted to make and interpret observations bearing upon the relation of precipitation to stream flow. Among the suggested studies having this purpose in view are the following:

"(1) Annual snow surveys in the drainage areas of Sierra Nevada streams, (2) snow movement subsequent to precipitation, (3) the relation of temperature, forest trees, drifting, etc., to snow melting, (4) the detailed relation between topography and precipitation, (5) water evaporation from lakes or reservoirs, (6) evaporation from snow, (7) establish, maintain, and observe snow and rain gages at isolated points which can be reached only at long intervals, (8) any other investigations of practical value in the solution of the water supply and flood protection problems of the State."

A study of the influence of volcanic dust veils on climatic variations, H. Arctowski (Science, n. ser., 41 (1915), No. 1050, pp. 252-255).—Reviewing especially the effects of volcanic eruptions of 1883 (Krakatoa), 1902 (La

Sonfrière, Pelée, and others), and 1912 (Katmai) on atmospheric temperature, with particular reference to his theory of pleionian variations (E. S. R., 31, p. 717), the author concludes that "the dust veil produced by the Krakatoa cruption affected atmospheric temperature very greatly. The violent volcanic cruptions of 1902 as well as the Katmai cruption of 1912 influenced the yearly mean temperature but very slightly or not at all. The pleionian variations of temperature have nothing in common with the presence or absence of volcanic dust veils."

A report on Montana climate, E. Burke and R. M. Pinckney (Montana Sta. Bul. 99 (1914), pp. 143, pl. 1, figs. 57; [Appendix] (1914), pp. 67-143).—This bulletin contains a compilation of observations on temperature and precipitation by the experiment station at Bozeman and by the U. S. Wenther Bureau at 37 other places in the State especially selected because of their geographic location and the length and completeness of their records. No place having a continuous record of less than ten years is included.

The more striking features brought out by the meteorological data are briefly summarized and illustrated by means of diagrams. In general Montana climate "clearly shows the characteristics of temperature due both to proximity to the Pacific Ocean and to its midcontinent situation; the former most marked in the west, the latter in the east. The influence of the north wind is predominant in winter over the plains region but is limited in the eastmountain district by the protective position of the lesser mountain ranges and combated by the warm winds from the Pacific Ocean, which modify the climate west of the Continental Divide and even extend their influence across the mountains.

"The total yearly precipitation of Montaua varies from about 22 in, in the western part of the State to about 14 in, in the eastern. The greater precipitation is generally at the higher points, the lesser on the lower lands.

"The direction of this variation indicates that most of the rainfall of the State has its origin in the moisture-laden winds from the Pacific. The eastern part of the State receives less rain than the central and western, but a greater portion falls in the growing season. This fact tends to equalize the crop value of the rain at different points."

A study of the oldest and most complete records furnishes no evidence that the yearly precipitation is increasing, as many people believe. As regards temperature, it is stated that "the high portion of the State has less extremes of temperature, greater rainfall, and less wind.

"The lower altitude has greater extremes of temperature, less rainfall, more wind, and a longer growing season free from frost. The rainfall is so small that even though it comes at a favorable time it must be rightly used to secure good crops. This consideration involves selecting proper crops to use the rain at the time it comes and proper means to secure absorption of the water into the soil and to keep it there until it is needed by a useful crop."

The appendix gives monthly temperature records for 1898-1913.

[Weather observations and notes], M. A. BLAKE, B. D. HALSTED, ET AL. (New Jersey Stas. Rpt. 1913, pp. 174-178, 611-614).—The general weather conditions of the season of 1913 at the college farm at New Brunswick are described and data for temperature and precipitation for that year and for a number of preceding years are tabulated.

Meteorology, R. F. Stupart (In Twentieth Century Impressions of Canada. London: Sells, Ltd., 1914, pp. 164-176, fig. 1).—The meteorological and climatic conditions of Canada as a whole and of each of its provinces are summarized. The outstanding fact disclosed is that the climatic conditions are extremely varied but that the continental type of climate largely predominates, only the

immediate coastline of British Columbia having a climate of marine type such as that of northwestern Europe.

Salton Sea water, A. E. Vinson and C. N. Catlin (Arizona Sta. Rpt. 1913, pp. 272-274).—In continuation of previous examinations (E. S. R., 29, p. 415), a complete analysis was made of a sample of Salton Sea water taken June 18, 1913, at the usual place southwest of Mecca, California.

The results show that from June 10, 1912, to June 18, 1913, the total solids in the water increased from 846.55 parts to 1.002.56 parts per 100,000. The water may now be considered as a 1 per cent brine. As in the previous year, calcium again showed a marked decrease, and the figures indicate that potassium is disappearing at a rapidly increasing rate. The ratio of potassium to sodium and total solids was 1:94:288 respectively in 1913, whereas the ratio in 1912 was 1:71.1:222 and in 1911 1:59.8:188.

The Salton Sea, D. T. MacDougal (Amer. Jour. Sci., 4, ser., 39 (1915), No. 231, pp. 231-250, figs. 6).—This article is condensed from the above.

Chemical composition of the water of Salton Sea and its annual variation in concentration, 1906–1913, W. H. Ross and A. E. Vinson (Carnegic Inst. Washington Pub. 193 (1914), pp. 35–48).—The investigations upon which the articles here referred to are based have already been noted from other sources (see above).

SOILS—FERTILIZERS.

Distribution of soil particles, DUKE OF BEDFORD and S. U. PICKERING (Woburn Expt. Fruit Farm Rpt., 14 (1914), pp. 37-45, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Ptant Diseases, 5 (1914), No. 9, pp. 1164, 1165).—A series of experiments to determine the influence of the rainfall on the distribution of the clay particles in a soil are reported. The samples were taken at monthly intervals at three depths of 6 in. each from a soil which had received moderate applications of artificial fertilizers for 18 years.

The amounts of suspended matter, after shaking the samples in water at intervals for 24 hours and allowing to settle for four hours, were found to vary considerably, the variation being greatest in the top 6 in, and least in the third 6 in. The latter contained more fine particles than the upper two layers together and a larger proportion of these was true clay. With one exception, an intimate relationship was found between the relative proportions of fine matter in the top 6 in, of soil and the inches of rainfall in the preceding 20 days, a larger proportion being found in the top soil after an increased rainfall and a smaller proportion after a decreased fall. The rainfall records for the preceding 30 days showed a similar but not so marked an agreement with the proportion of fine matter, from which it is concluded that the effect of the rainfall had partially worn off after 20 days.

It was found that if the upper and second depths of 6 in, are alone considered, the relative proportions of fine particles in the top layer do not follow the rainfall records so closely as when the whole 18 in, are considered, from which it is concluded that the effect of rain on the fine particles extends below the top 12 in. It is further concluded "that the actual amount of fine particles in the top layer, though perhaps the most important feature of the effect of the rainfall, is not the sole one, and that some redistribution of the fine particles also occurs... It is evident that in this effect of rain on the flocculation of the soil, we have a factor which is amply sufficient to cause considerable difference in the behavior of plants in the same soil on different occasions."

The decomposition products of the aluminum silicate rocks, particularly the laterites of Madagascar, A. Lacroix (Compt. Rend. Acad. Sci. [Paris],

159 (1914), No. 18, pp. 617-622).—The author compares the modes of decomposition of the aluminum silicate rocks of Madagascar and West Africa.

In West Africa he distinguishes two zones of decomposition, namely, the so-called zone of separation in which decomposition is governed by the nature of the original rocks and above it the zone of concretion. In the first zone in the case of gabbros, diabases, and the nepheline syenites most of the silica, lime, magnesia, and alkalis are eliminated and crystalline aluminum hydrate produced. In the case of granites, gneisses, and mica-schists the decomposition is progressive, first producing an aluminum silicate, sometimes crystalline but more frequently colloidal, which is little by little transformed into the colloidal hydrate. In the zone of concretion silica and other elements are eliminated and in most cases the tendency is toward the formation of progressively pure aluminum hydrate in both crystalline and colloidal forms. The iron accompanying aluminum hydrate is usually in the hydrate form and moves by degrees from the lower to the upper zone where it accumulates, thus tending to form an iron crust at the surface.

The iron crust is usually absent from the Madagascar soils. The surface soils are most frequently red soils and decomposition is not governed entirely by the nature of the original rock. The laterization of diabases, basalts, and syenites is similar to that in the zone of separation in African soils, and gueisses, micaschists, and granites are most frequently transformed into aluminum silicate and colloidal aluminum hydrate, which is the most frequent cause of the red soils. Granite and pegmatite are sometimes transformed into kaolin, free aluminum hydrate, and colloidal aluminum silicate. Another frequent mode of decomposition not observed in Africa consists in the production from granite of clear white laterite containing undecomposed quarts. The author concludes that the red soils of Madagascar are not laterites but lateritic clays and frequently only common clays.

Soils of the Sassafras series, J. A. Bonsteel (U. S. Dept. Agr. Bul. 159 (1915), pp. 52, pls. 9, fig. 1).—This bulletin deals with the distribution, characteristics, crop adaptabilities, and fertility requirements of the soils of the Sassafras series, which are confined in their distribution to the northern portion of the Atlantic Coastal Plain, extending from the southern end of the Chesapeake Bay region through central and southern New Jersey to the western end of Long Island, New York.

The different soil types of the series range in texture from a gravelly loam through sands and sandy loams to a heavy silt loam, and consist of water-laid materials, chiefly formed as marine, estuarine, and fluvial terraces, but including some areas formed by the deposition of glacial outwash materials. They are distinguished by the yellow or brown color of the surface soils, by the yellow or reddish-yellow color of the subsoils, and by the prevalence of an underlying layer of gravel or gravelly sand at depths of from 2 to 6 ft. or more.

"The drainage of the soils of the . . . series is generally good and only the more level areas and those remote from stream channels are decidedly in need of artificial drainage. . . . The chief requirements for the improvement of crop yields upon the different types . . . are the more extended use of stable manure, supplemented with the plowing under of green-manuring crops; the use of lime in some form, particularly in conjunction with the growing of the leguminous forage and green-manuring crops; the adoption in some sections of a crop rotation which shall provide for the alternation of grass crops with the prevalent system of grain growing; and local underdrainage on small areas of the heavier textured types. [These] soils . . . are suited to intensive tillage for the growing of market garden and truck crops upon the more sandy types, while the heavier

types constitute the best soils for the production of the staple crops to be found within the northern portion of the Atlantic Coastal Plain,"

Soil survey of Habersham County, Georgia, D. D. Long and E. C. Hall (U. S. Dept. Agr., Advance Sheets Field Operations of the Bureau of Soils, 1913, pp. 48, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture, was issued December 31, 1914. It deals with an area of 181,120 acres in northeastern Georgia, which lies partly in the Blue Ridge Mountains and partly in the Piedmont Plateau, the topography ranging from The greater part of the county is drained by the rolling to mountainous. Chattahoochee River system. The soils are residual and alluvial. Twenty types of seven series and two miscellaneous types are mapped. The most important soil series in the county is the Cecil series, including six soil types of which the clay loam is the predominating type in the Piedmont section. "The agricultural progress of this county is dependent upon the maintenance of the productiveness of the soils by a greater diversification of crops, the use of crop rotations, the more extensive use of cowpeas and other legumes, the incorporation of organic matter with the soil, the keeping of more live stock upon the farms, the exercise of care in seed selection, and the proper mixing and use of fertilizers."

Soil survey of Jones County, Georgia, D. D. Long, G. A. Crabb, et al. (U. S. Dept. Agr., Advance Shects Field Operations of the Bureau of Soils, 1913, pp. 44, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture, was issued December 31, 1914. It deals with an area of 256,640 acres in central Georgia, approximately 80 per cent of which lies in the Piedmont Plateau and the remainder in the Coastal Plain. topography varies from level to undulating divides to hilly and broken areas and the drainage is performed by the Ocmulgee and Oconee river basins. The soils range from incoherent coarse sands to stiff heavy clays. three types and three phases of thirteen series are mapped, of which nine types and the three phases are found in the Piedmont section and are said to represent the best general farm soils in the county. The Cecil soils are the most productive, with the Greenville and Orangeburg soils ranking next. stated that the organic matter content of practically all the soils has been depleted by the continuous growing of clean culture crops and the limited appreciation of the value of systematic crop rotation and of the growing of leguminous crops.

Soil survey of Talbot County, Georgia, R. A. WINSTON and H. W. HAWKER (U. S. Dept. Agr., Advance Sheets Field Operations of the Bureau of Soils, 1913, pp. 40, fig. 1, map 1).—This survey, made in cooperation with the Georgia State College of Agriculture, was issued October 20, 1914. It deals with an area of 247,680 acres in west-central Georgia, the topography of which ranges from gently rolling and undulating to very rolling and hilly. All sections of the county are adequately drained. The soils are of residual, sedimentary, and alluvial origin. Twenty-four soil types of eleven series are mapped of which the Cecil clay loam is the most important. It is stated that the soils of the county are generally in need of liming and more thorough cultivation and that terracing is necessary over the more rolling areas. "There is little recognition of the adaptation of soils to crops and no systematic rotation of crops, while the improvement and maintenance of the productiveness of the land receives but little attention."

Agriculture of Sulphur Spring Valley, Ariz., R. H. Forbes (Arizona Sta. Bul. 72 (1913), pp. 213-224).—This is a reprint of a chapter from a bulletin of the U. S. Geological Survey which has been previously noted (E. S. R., 30, p. 18).

Soil erosion, C. T. Ames (Mississippi Sta. Bul. 165 (1914), pp. 3-12, figs. 7).— Experiments at the Holly Springs substation farm on the prevention of soil erosion are described.

The soil is the so-called brown loam with white impervious clay and a reddish soil resembling sandstone for subsoil. Small gullies were filled with team and plow and drag scraper, or by dynamiting. The former method was found to be the cheaper. When the gullies are much larger it is stated that satisfactory results can be had by running terraces about 75 yds. apart on the hillsides, forming a system of ponds to catch the wash soil, and which are joined together by drains to carry off the surplus water during rains. "To prevent soil washing, anything that will hold the soil in place, such as a sod of bermuda or lespedeza, is excellent; any device that will control the running water so as to make it move slowly is more or less helpful and satisfactory." The system of terracing, in which by means of rows and embankments the water is made to run more slowly, is considered the best system to use on clay soils in the South where rainfall is heavy.

The laying off and construction of terraces is also described.

Description of a wire cage used for the protection of pot experiments, J. G. LAPMAN ET AL. (New Jersey Stas. Bul. 269 (1914), pp. 18-20. pl. 1; Rpt. 1913, pp. 484-486, pl. 1).—Details of the construction of this cage are given.

The influence of bacteria supplied in manure on the decomposition of green manure, J. G. LIPMAN ET AL. (New Jersey Stas. Bul. 268 (1914), pp. 22-25; Rpt. 1913, pp. 474-477).—This is a continuation of experiments, the first five years of which were summarized in the report of the station for 1912 (E. S. R., 30, p. 325).

The results show that applications of from 1,000 to 4,000 lbs, per acre of manure gave little or no increase on plants receiving leguminous (crimson clover) green manures but produced quite different results on plats receiving nonleguminous (rye) green manures. The results in the latter case confirmed those of the previous experiments in showing that greater increases in every case resulted from small applications of manure alone than could be accounted for by the plant food supplied, thus tending to confirm the conclusion "that the bacteria conveyed in small quantities of cow manure are instrumental in bringing about a more rapid decomposition of the green manure crop, and thus make available more nitrogen for the succeeding crop."

Oxidation of manganous carbonate by microbes, M. W. Beijerinck (K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdeel., 22 (1913–14), pt. 1, pp. 415–420; also in ditto Proc. Sect. Sci., 16 (1913–14), pt. 1, pp. 397–401; abs. in Chem. Abs., 8 (1914), No. 12, p. 2211).—The results of tests show that culture plates of agar containing about 1 per cent of manganese carbonate develop brown spots when inoculated with garden soil, indicating the oxidation of the manganese by bacteria or by some of the fungi present in the soil. Apparently very different species of fungi are capable of producing such oxidation, but all of the species are among those commonly found in humus.

Investigations into the nitrogen metabolism of soil, H. H. Green (Centbl. Bakt. [etc.], 2. Abt., 41 (1914), No. 18-23, pp. 577-608; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 623, I, pp. 1113, 1114).—In a continuation and extension of work by Löhnis (E. S. R., 17, p. 1048) the author reports laboratory experiments on ammonification, nitrification, nitrogen fixation, and cyanamid decomposition in both soil and solution media carried out on samples of soil taken at approximately monthly intervals throughout the year, with particular reference to the influence of season and of soil cultivation. A slight seasonal variation is shown.

As regards the ammonification of the organic manures flesh meal, horn meal, and blood meal, the bacterial activity showed a rise from August to October, a tendency to fall or remain constant in November, and a rise to a maximum in December. This was followed by a minimum in February and a low maximum in April, and from April to July there was a slight fall, which was probably continued to a summer minimum in August. Similar results were obtained as regards nitritication, except that the spring maximum occurred in March and the decline to a summer minimum commenced in April. The slight variations in ammonification and nitrification and the December maximum are attributed to the mild character of the winter. Nitrogen fixation in 1 per cent mannite solution was low with the soil samples of August and September. Subsequently it was fairly constant except with samples taken after plowing. No definite results were obtained in the cyanamid experiments.

"Comparison of the results of manuring experiments in the field with those of laboratory tests indicates that the latter may be of considerable value in affording information as to the decomposition processes naturally occurring in soils. No difference, however, could be detected between soil from one-half of the experimental area which had received autumn cultivation and soil from the other half which remained untouched until the spring plowing, although the crop returns showed a 20 per cent superiority (in respect to nitrogen) in favor of autumn cultivation."

Solution methods were found to be equal to those in which the natural soil is employed as a medium. As regards nitrification, the solution method gave much clearer indications of seasonal variation, while the seasonal variation in ammonification was more clearly indicated in soil tests.

Nitrogen fixation by Azotobacter in substrata poor and rich in nitrogen, J. Hanzawa (Centbl. Bakt. [etc.], 2. Abt., 41 (1914), No. 18-23, pp. 573-576; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 623, I, p. 1113).—Further studies along the line of those reported by Lölmis and Green (E. S. R., 31, p. 120), including a test as to the value of humus as a source of energy in the nitrogen fixing process, are reported.

Mixed cultures of different strains of Azotobacter were found to be more effective in nitrogen fixation than the same bacteria in pure cultures, especially in aqueous solutions of maunitol.

The nitrogen of humus, even in large quantities, had no serious retarding effect on the fixation of nitrogen by pure cultures of Azotobacter. Small amounts of nitrates also had almost no effect, but when present in amounts corresponding to amounts of nitrogen greater than 2.5 per cent of the carbon, nitrogen fixation was retarded and finally inhibited. It is thought probable that the soil nitrogen can only in special cases, if at all, have an unfavorable effect on nitrogen fixation.

The humus of stable manure was capable of being utilized as a source of energy in nitrogen fixation, while that of green manure was not.

Mutual influence of certain crops in relation to nitrogen, K. F. Kellerman and R. C. Wright (Jour. Amer. Soc. Agron., 6 (1914), No. 4–5, pp. 204–210, figs. 4).—A brief account is given of pot experiments with legumes and nonlegumes grown singly and combined which showed "that the effect of a given crop upon two different soils may be very different, both in regard to its effect upon the total soil nitrogen and upon the nitrifying power of the two soils." There was an actual loss of soil nitrogen in the case of the nonlegumes, especially barley, over and above that utilized by the plants. With the legumes there was no such loss, but in some cases a gain. Where combinations of legumes and nonlegumes (beans and barley, and peas and barley) were grown both the legume and the nonlegume showed an appreciable gain in nitrogen.

The influence of the mechanical composition of the soil on the availability of nitrate of soda and dried blood, J. G. Lapman et al. (New Jersey Stas. Bul. 268 (1914), pp. 5-19, figs. 5; Rpl. 1913, pp. 458-471, figs. 5).—This is an account of a continuation during 1913 of experiments begun in 1911 (E. S. R., 30, p. 324). The results are summarized as follows:

"When sand was mixed with shale soil (Penn loam) in varying proportions, the yield of dry matter and the percentage of nitrogen recovered from nitrate of soda were greater with 10 to 70 per cent of sand than they were with the shale soil alone, or with 80, 90, or 100 per cent of sand. The highest yield of dry matter and percentage of nitrogen recovered occurred with 50 per cent of sand.

"With dried blood the yield of dry matter and the percentage of nitrogen recovered were higher in pure sand, and in all dilutions, than with the shale soil alone.

"In no case was the yield of barley (first crop) on the check cylinders as high as the yields on the cylinders that received nitrate of soda and dried blood.

"With the residual crop of buckwheat no nitrogen was recovered from three of the series that received nitrate of soda, while comparatively small amounts were recovered from the other series. With dried blood there was some recovery in all series, the highest occurring in Series 'D' with 30 per cent of sand.

"With the first crop, barley, the highest average yield of dry matter and nitrogen was from the nitrate of soda cylinders; with the residual crop of buckwheat the highest average yield of dry matter and nitrogen was from the dried blood cylinders. With the combined crop the average yield of dry matter and nitrogen were very nearly the same for the two nitrogenous materials. For the check cylinders, the average yield of dry matter and nitrogen was slightly higher with the residual crop than with the first crop.

"The fact that the average yield of dry matter and nitrogen for the combined crops was about the same with nitrate of soda and dried blood does not necessarily lead to the conclusion that these two materials are equally good for all types of soil. In the discussion it has been shown that for the shale soil, and dilutions up to and including 70 per cent of sand, the average availability of dried blood is 70.6 when nitrate of soda is placed at 100, while, with 80 to 100 per cent of sand, the average availability of dried blood is 250 when nitrate of soda is placed at 100. From this it must be inferred that for all except very sandy soils nitrate of soda shows a higher availability than dried blood.

"The average percentage of nitrogen in the dry matter is higher for both crops with nitrate of soda than with dried blood or with the check cylinders.

"With most soils we need not expect much residual effect from moderate applications of nitrate of soda. We may expect some residual effect from dried blood in nearly all cases.

"The actual net recovery of nitrogen from the humus of the shale soils to which varying amounts of sand had been added is greater in every case than the theoretical amount as calculated from the recovery from pure shale soil. Mixing sand with heavy soils permits better aeration and drainage and results in a more complete utilization of the nitrogen in the organic matter."

[Production and consumption of Chilean nitrate] (Assoc. Sal. Propaganda, Circ. Trimest. 62 (1914), pp. LII+V+431).—This is a detailed report on the nitrate of soda industry of Chile for the year ended June 30, 1914. It is stated that the production of nitrate during that year was 3.165.989 short tons as compared with 3.020.083 tons the previous year. The exportation was 2.984.565 tons as compared with 2,971,412 tons the previous year. The consumption was 3.002,271 tons as compared with 2,791,336 tons the previous year.

Nitrate production, A. B. Easterling (U. S. Dept. Com., Com., Rpts., No. 3 (1915), p. 48).—The marked decrease in export duties in Chile during the past year is attributed largely to the decreased production of nitrates. The production of nitrate steadily decreased during the months of August and September, until in the latter month it was only 51 per cent of the amount produced in July. The export in September, 1914, was 107,238 tons as compared with 208,417 tons in September, 1913.

Chilean nitrate statistics, J. D. Myers (U. 8, Dept. Com., Com. Rpts., No. 11 (1915), p. 196).—Statistics are briefly summarized showing a pronounced decrease in number of plants and a falling off in production and exports since the beginning of the European war. It is stated that the production during the five months July to November, 1914, was 961,405 tons as compared with 1,275,093 tons during the corresponding period in 1913. Fifty-four plants were in operation in November, 1914, as against 127 in November, 1913.

Nitrate of soda in 1914 (Chem. Trade Jour., 56 (1915), No. 1444, pp. 69, 70).—It is stated that the production of Chilean nitrate was 2.432,320 tons in 1914 as compared with 2.739,480 tons in 1913; the exports, 1.824,760 tons in 1914 as against 2.705,820 tons in 1913; stock on hand in Chile December 31, 1.091,700 tons in 1914 as compared with 499,750 tons on the same date in 1913; cargoes in nitrate ports December 31, 1914, 38,700 tons. There was an increase of 122,000 tons in nitrate deliveries during the first half of 1914 over those of the same period of 1913. Of the 170 nitrate plants in Chile, only about 40 remained in operation at the end of 1914. "Of the year's total, 1,721,000 tons were produced in the first seven and only 711,320 tons in the succeeding five months, against 1,608,600 tons and 1,130,880 tons, respectively, in the corresponding periods in 1913."

Figures for consumption can not be given under present circumstances.

Sulphate of ammonia in 1914 (Chem. Trade Jour., 56 (1915), No. 1444, pp. 66, 71, 72).—Prices of ammonium sulphate were lower in 1914 than in any year since 1905, but as a result of the European war the prices rose in October and remained substantially uniform until the end of the year. The production in England in 1914 was 421,000 tons as compared with 432,000 tons in 1913. The German production is not known, but it was increasing slowly up to August, 1914. Figures are also lacking for other producing countries except the United States, in which the estimated output was 183,000 tons in 1914 as compared with 195,000 tons in 1913. Imports by the United States from July to December, 1914, were almost equal to those of the same period of 1913.

[German potash salts] (Oil, Paint, and Drug Reporter, 87 (1915) No. 7, pp. 9, 10, 60).—It is suggested that the strict enforcement of the German embargo on potash may be relieved by permitting shipment of potash salts after they have been subjected to some sort of denaturing process, the nature of which is not disclosed, which will preclude their use for any purpose except as fertilizer. The imports of muriate of potash by this country during the 5 months (August to December, 1914) were 25,813 tons valued at \$004.043; for the corresponding period of 1913 they were 98,781 tons valued at \$3.217.847. The corresponding figures for sulphate of potash were 8,499 tons valued at \$382,202 for 1914 and 17,896 tons valued at \$739,327 for 1913. The total imports of potash salts during the years ended December 31, 1913 and 1914, were 942,442 and 702,810 tons, respectively.

Potash supplies from Germany (U. S. Dept. Com., Com. Rpts., No. 32 (1915), p. 529).—It is stated that the German potash syndicate on February 1, 1915, "decided to form a commission to consider means for denaturizing potash salts so as to preclude the possibility of using them for ammunition and

military purposes and making them valuable only as fertilizers. Upon the receipt of the report of the commission the potash syndicate will confer with the Government relative to moderating the embargo on potash. . . .

"The United States imported during the fiscal year ended June 30, 1914, German potash salts for fertilizers aggregating 1.066,929 tons gross, equivalent of 256,979 tons of potash ($\rm K_2O$). Importations for the six months July 1 to December 31, 1914, totaled only 184,192 tons, against 567,595 tons during the similar period of 1913, thus leaving a shortage on January 1, 1915, of 383,403 tons."

Vegetation experiments, J. G. LIPMAN ET AL. (New Jersey Stas. Bul. 269 (1914), pp. 12-18, pl. 1; Rpl. 1913, pp. 478-484, pl. 1).—Pot experiments, making comparative tests of a so-called rock potash fertilizer with other fertilizing materials and of basic slag with other phosphates are reported.

In the first case the rock potash fertilizer appears to have had a depressing effect upon the yield of dry matter. It is suggested that in view of the fact that this product is a low-grade material and must be used in comparatively large amounts it is possible that other soluble compounds are introduced in sufficient amounts to prove toxic.

In the comparison of phosphatic fertilizers the greatest increase resulted from the use of one of the basic slags, the lowest from rock phosphate. The test included comparisons of four different samples of the slag with acid phosphate, double superphosphate, sodium phosphate, and blue rock phosphate.

Comparison of magnesian and nonmagnesian limestone in rotation experiments, J. G. Lipman et al. (New Jersey Stas. Bul. 267 (1914), pp. 5-49, fig. 1; Rpt. 1913, pp. 421-457, fig. 1).—This is an account of a continuation of experiments begun in 1908, in which "four five-year rotations were carried out on 28 one-twentieth acre plats, so arranged that for each rotation there was a check plat and three plats which received nonmagnesian limestone at the rate of $\frac{1}{2}$, 1, and 2 tons per acre, and three plats which received like amounts of magnesian limestone. At the close of the rotation, samples of soil were collected from the various plats and the lime requirement for each determined.

"The results show that nearly all the plats were acid at that time. With but few exceptions, however, the acidity decreased as the amount of applied lime increased. The check plats showed the highest lime requirement.

"A comparison of the amount of nitrogen present in the surface $6\frac{2}{3}$ in, at the close of the rotation, with the amount present soon after the experiment was started, indicates a gradual loss of nitrogen. That is, with an annual application of nitrogenous fertilizers and with the use of two or more leguminous crops in the rotation, the nitrogen supply was not maintained.

"With comparatively few exceptions, both forms of lime resulted in an increased crop yield over the check plats, the most notable exceptions being the potatoes which were grown in two of the rotations.

"The yields were usually somewhat higher with the magnesian than with the nonmagnesian limestone.

"One tou of nonmagnesian limestone gave about the same increase as one-half ton, but two tons gave a decidedly greater increase than one ton,

"One ton of magnesian limestone gave, in most cases, higher yields than a half ton, but two tons did not materially increase the yield over one ton.

"In the majority of cases, the dry matter of the crops from the limed plats showed a higher percentage of nitrogen than that from the unlimed plats. This is important in the case of feeding materials and human foods, inasmuch as it means a higher protein content,

"The value of the total increased yield on the limed plats, as compared with the yield on the check plats, varies from a few dollars to \$50 or \$60 per acre for the five years according to the crops in the rotation. In the majority of cases the increased value is more than \$20. This should be regarded as a good investment on the money expended for the limestone—that is, the cost of one application varying from 0.5 to 2 tons per acre for the entire five years."

Methods and results in vegetation experiments, J. G. Lipman and A. W. Blanc (New Jersey Stas. Bul. 269 (1914), pp. 5-11).—Two series of pot experiments with radio-active material on barley are reported. In the first the material was used at rates of 0.1, 0.2, and 0.3 gm, per pot containing 20 lbs. of sand with which had been mixed 8 gm, of acid phosphate, 4 gm, of potassium sulphate, 5 gm, of calcium carbonate (ground limestone), 0.5 gm, of magnesium sulphate, and 0.25 gm, of iron sulphate. In the second the material was used at rates of 0.05, 0.1, and 0.15 gm, per pot containing 9 lbs. of gravelly loam soil to which had been added 4 gm, acid phosphate, 2 gm, potassium sulphate, 1 gm, nitrate of soda, and 5 gm, of ground limestone. In neither case did the radio-active material show any appreciable effect.

Utilization of the fish waste of the Pacific coast for the manufacture of fertilizer, J. W. Turrentine (U. S. Dept. Agr. Bul. 150 (1915), pp. 71, pls. 6, fgs. 2).—This is a part of a general inquiry as to the fertilizer resources of the United States and their utilization. It deals with the technology and waste of fish, especially salmon, in canning, but discusses particularly the fertilizer value of the waste and methods of utilizing it for the preparation of fish scrap or of a mixed fertilizer with kelp. Brief reference is also made to the preparation of fish scrap from the herring, tuna, whale, halibut, and sardine fisheries of the Pacific coast, with analyses of dried fish scrap from sardine, whale, tuna, and dogfish fisheries.

The waste from the salmon fisheries "is variously estimated to be from 25 to 50 per cent of the original or 'round' weight of the fish." The total waste from this source on the Pacific coast is stated to be 140,210 tons valued at \$2,103,150.

The average composition of the raw waste-from the mechanical dressing of "humpback" salmon was found to be nitrogen 3.02, phosphoric acid 1.59, moisture 64.6, and oil 10.43 per cent.

Of the total amount of waste only 800 tons were utilized on the Columbia River in 1913 and 15.500 tons around Puget Sound, the product being 1.630 tons of dried fish scrap and 286,000 gal. of oil. The scrap showed nitrogen varying from 7.63 to 9.49 per cent, averaging 8.7 per cent; phosphoric acid, from 5.32 to 12.08 per cent, averaging 8.31 per cent; moisture, from 3.91 to 5.36 per cent, averaging 4.97 per cent; and oil, from 8.32 to 20.02 per cent, averaging 14.32 per cent. Menhaden scrap shows as the average 8.43 per cent of nitrogen, 6.69 of phosphoric acid, 7.72 of moisture, and 6.99 of oil.

As the most efficient means of conserving the waste the author recommends as an alternative of the central rendering station, which has generally failed to meet the requirements of the situation, a small unit by-products plant of low capacity, just sufficient to treat the waste of the cannery of which it forms a part. In order that the plant may be continuously and profitably employed it is suggested that it may be utilized when the canning season is ended in preparing kelp for fertilizing purposes. A report on the fish scrap industry of the Atlantic coast has been previously noted (E. S. R., 30, p. 326).

Report on commercial fertilizers, 1914, E. H. JENKINS and J. P. STREET (Connecticut State Sta. Rpt. 1914, pt. 2, pp. 43-112).—Analyses and valuations of 776 samples of fertilizers collected and examined during the 1914 inspection are reported, with notes on the source and character of the raw materials and miscellaneous fertilizing materials examined, the latter including sheep manure.

muck or peat, leaf mold, apple pomace, lime, limestone, and wood ashes. An analysis of sludge from the manufacture of lime-sulphur spraying solutions is appended.

Inspection of commercial fertilizers, 11. D. Haskins et al. (Massachusetts Sta. Control Ser. Bul. 2 (1914), pp. 98).—This is a detailed report of fertilizer inspection in Massachusetts during 1911, including analyses and valuations of 606 brands of mixed fertilizers, raw fertilizing materaials, and lime compounds. The bulletin discusses commercial shortages in both unmixed fertilizing materials and mixed goods and the quality of plant food in the mixed goods, shows the general standing of each manufacturer's brands, and emphasizes the economy of purchasing only high-grade fertilizers.

A brief account is given of a vegetation experiment made to show the efficiency of the alkaline permanganate method as a means of indicating the activity of water-soluble organic nitrogen, and the general quality of nitrogen found in each manufacturer's product is shown. Results of field tests of certain mineral or stone meal fertilizers are briefly reported.

Commercial fertilizers, J. L. Hills et al. (Fermont Sta. Bul. 182 (1914), pp. 265-339).—Analyses and valuations of 185 brands of fertilizers representing the output of 18 companies licensed to sell in Vermont in the season of 1913-14 are reported.

The quality of the fertilizers was fairly satisfactory, 83 per cent of the brands meeting their guaranties and the quality of the crude stock used apparently being good. All but eight of the brands containing nitrogen carried mineral as well as organic forms of nitrogen. The average selling price of the fertilizers examined was \$32.53; the average valuation, \$20.35. The high-priced brands were most economical as regards plant food obtained for the price paid. A comparison of analyses of brands for three years shows in most cases essential evenness, but in some cases considerable variation in composition.

AGRICULTURAL BOTANY.

Plant physiology, L. Jost. trans. by R. J. H. Gibson (Oxford: Clarendon Press, 1913, pp. 168, pl. 1).—This is a supplement to the English translation previously noted (E. S. R., 19, p. 529) giving the alterations or additions contained in the second edition of the German original. A large amount of additional literature is also cited.

Students' handbook to accompany Plants and Their Uses, F. L. SARGENT (New York: II. Holt & Co., 1914, pp. 80, figs. 17).—This book consists of laboratory directions for studies to be conducted in connection with the author's book on Plants and Their Uses (E. S. R., 31, p. 425).

Experiments on hybridization with Canna indica, J. A. Honing (K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdeel., 22 (1913-14), pt. 2, pp. 773-779, figs. 8; also in ditto, Proc. Sect. Sci., 16 (1913-14), pt. 2, pp. 835-841, figs. 8).—An account is given of experiments in hybridizing two varieties of Canna, one of which was characterized by having green leaves, bracts, stems, etc., the other darker leaves with a red edge and dark red flowers. The behavior on the different crosses is shown and the proportions of the different hybrids suggest a segregation according to three Mendelian factors.

[Some correlation studies of hypocotyls], B. D. Halsted et al. (New Jersey Stas. Rpt. 1913, pp. 588-611, pl. 1).—The results are given of studies on the lengths of hypocotyls and first internodes in tomatoes, peppers, and eggplants, of the influence of varietal qualities upon the length of hypocotyl and the first internode in beans, the influence of the depth of planting and hilling beans, the

effect of limited shade, varietal influence upon the length of hypocotyl and tirst internode, the influence of pod position of seeds upon length of hypocotyl and vigor of the plant in soy beans and pen beans, and a study of the relation of sex to the length of hypocotyl in hemp. Notes are also given on the rise of the zone of geotropic response in seedlings and of an experiment in the selection of Wilson soy beans.

A peculiar negative correlation in Enothera hybrids, G. H. Shull (Jour. Geneties, 4 (1914), No. 1, pp. 83-102, pls. 2, fig. 1).—Referring to difficulties in applying to Enothera the rules of genetic behavior demonstrable in other groups of organisms (suggesting a hereditary mechanism in this genus fundamentally different from that which distributes the Mendelian unit characters), and noting an apparent inadequacy of the data previously recorded for discovery of the essential features of this mechanism, the author presents and discusses data obtained by himself in studying the progeny of three rosettes from unguarded but probably pure bred seeds of E. rubricolyx since 1912, both in pure strain and in crossing with other forms.

It is held that three conclusions arrived at by Gates (E. S. R., 25, p. 327), regarding the origin and genetic nature of the *E. rubricalyx* character are erroneous, namely, that the character represents a purely quantitative difference from *E. rubrinervis*, that it differs from the latter species in a single monohybrid Mendelian unit, and that the nature of a character itself, instead of the nature of the inheriting mechanism to which it is related, determines the manner of inheritance of that character.

Some fundamental morphological objections to the mutation theory of De Vries, E. C. Jeffrey (Amer. Nat., 49 (1915), No. 577, pp. 5-21, figs. 7).—As a result of his studies the author concludes that the Onagraceæ are largely characterized by hybrid contamination in nature. This holds particularly for Enothera lamarekiana and other species of this genus, which serve as the basis of the mutation hypothesis of De Vries. The species of Enothera, the author says, are to a large extent, if not wholly, crypthybrids, and in his investigations the objection raised by Bateson to the genetical purity of E. lamarekiana was confirmed. He considers hybridism the best explanation for the peculiar conduct of E. lamarekiana as well as other species of this genus in cultures.

The explanation of an apparent exception to Mendel's law of segregation, Tine Tammes (K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdeel., 22 (1913-14), pt. 2, pp. 846-857; also in ditto, Proc. Sect. Sci., 16 (1913-14), pt. 2, pp. 1021-1031; and Rec. Trav. Bot. Nécrland., 11 (1914), No. 1, pp. 54-69).— The author, from experiments in crossing white and blue flowering varieties of flax, found in the second and following generations white and blue individuals that were not in agreement with the numbers expected in accordance with Mendel's law of segregation. In all cases there was a deficiency in white flowering plants. This is believed to have arisen from two causes, (1) the F₂ generation and the heterozygotes forming too small a number of seeds to yield white flowering plants, and (2) the low germinating power of the seed.

The influence of position in the pod upon the weight of the bean seed, J. A. Harris (Amer. Nat., 49 (1915), No. 577, pp. 44–47, figs. 3).—Attention having been called to the significance of position in the pod as a factor in determining the weight of the bean seed, the author gives the results of a series of quantitative determinations of the relationship, basing his figures largely on data part of which have been previously given (E. S. R., 30, p. 433).

He claims that the percentage of ovules which develop into seeds increases from the base toward the stigmatic end of the pod. In small pods the rate of increase may be fairly regular, but in larger pods it falls off toward the stigmatic end, where the feemidity may be even lower than it is a little farther down in the pod.

Variation of structure and color of flowers under insolation, H. E. RAWSON (Abs. in Rpt. Brit. Assoc. Adv. Sci., 1913, pp. 711-713).—In pursuance of work previously noted (E. S. R., 21, p. 319), the author reports studies with nasturtium under controlled conditions as regards illumination, employing in addition to the descendants of South African plants previously used some grown from English seed.

Very decided changes in the coloring pigments are apparently accompanied by a tendency to sterility. A correlation is suspected between color of stem and that of subsequent flowers. The occurrence of fasciation is now common, as are also modifications in the mode of inflorescence. Plants of dwarf habit have appeared and have been propagated for three generations by screening, the unscreened seedlings soon reverting to the climbing habit. By permitting cross fertilization and by limited employment of screening it is said to be now easily possible to produce slight degrees of color modification. Certain structural characters which appeared have been transmitted. The sun's altitude, diurnal or seasonal, seems to produce not only in coloration, but also in metabolism, changes which can be reproduced in other individuals.

Adjustment to light in oats, W. H. Arisz (K. Akad. Wetensch. Amsterdam, Verst. Wis en Natuurk, Afdeel., 22 (1913), pt. 1, pp. 536-549; also in ditto, Proc. Sect. Sci., 16 (1913-14), pt. 2, pp. 615-628).—A study was made of oat plants grown in a dark room so regulated as to be maintained at a constant temperature and with varying illumination to determine the adjustment of the plant to different amounts of light.

The observations with bilateral illumination showed that by illuminating a plant, first on one side and then on the other, each stimulus results in a curvature, as long as there is a certain definite time intervening between the two exposures. If the illumination on the two sides should be simultaneous the tendency to curve would be neutralized and consequently the plant would grow in a straight line. Where the illumination was from all sides the growth showed a condition that is considered the summation of unilateral illuminations.

Electromotive phenomena in plants, A. D. Waller et al. (*Rpt. Brit. Assoc. Adv. Sci., 1913, pp. 241–258*).—The authors, referring to the tests and conclusions reported by Balls (E. S. R., 29, p. 27) as bearing upon their own work (E. S. R., 28, p. 731), state that previously they themselves have applied the test quantitatively only in selected cases. The present report contains a detailed account of work carried out recently to serve as an indication and sample of the procedure considered necessary in working out the test as a practical method of measuring the vitality of seedlings. Their data are held to indicate a general relation between plant vitality and voltage of blaze current.

On the regulation of the transpiration of Viscum album and Rhipsalis cassytha, Z. Kamerling (K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdeel., 22 (1913–14), pt. 2. pp. 821–835, pl. 1; also in ditto, Proc. Sect. Sci., 16 (1913–14), pt. 2. pp. 1008–1021, pl. 1).—Results are given of a study on the antagonism between the guard cells of the stomata and the adjacent cells of the epidermis in these plants.

It was found that in leafy boughs or whole plants allowed to wither the amount of transpiration per unit of time remains approximately constant until the bough is dried up, or the amounts decrease uniformly until transpiration is reduced to a minimum. In the study of the two parasitic plants enumerated above it was found that when they had lost a certain proportion

of weight, varying from 1 to 4 per cent, the amount of transpiration per unit of time increased. Later when the loss in weight had increased from 6 to 10 per cent transpiration decreased.

This increase in the intensity of the transpiration is attributed to the dilation of the openings of the stomata. The author states that the dilation is probably caused by the antagonism between the guard cells and the subsidiary cells of the stomata, so that the turgor in the subsidiary cells begins to decrease sooner than in the guard cells, thus causing a stronger curvature of the guard cells and dilation of the slit of the stomata,

Bark ringing and the descent of sap, J. M. Janse (Ann. Jard. Bot. Buitenzorg, 2. ser., 13 (1914), pt. 1, pp. 1-92, pts. 12).—A study has been made of the effect of bark ringing on the descent of the elaborated material in trees, particular attention being paid to the force and direction of the current. The experiments were made on horizontal branches so selected as to remove the force of gravity, and the primary and final changes, the reversal of the direction of the current, and the transportation of nonnutrient materials were studied.

In stems which were wounded by removing the bark in various ways, the cambium layer and the wound tissue were found to influence the movement of the elaborated material, and in addition to this, what the author calls a special force, the exact nature of which was not determined, was always active. This force is active in the secondary wood and assists in maintaining the current in the same general direction of the elements in the surface of the wood.

The destruction of paraffin by Bacillus prodigiosus and soil organisms, R. Greig-Smith (*Proc. Linu. Soc. N. S. Wales, 39 (1914), pt. 3, pp. 538–541).*—Certain bacteria and molds having been shown capable of utilizing certain hydrocarbons, the author has undertaken an experiment to determine whether this action may not be taken by *B. prodigiosus*. Dried blood, casein, and finally kieselguhr were coated with paraflin inoculated with *B. prodigiosus* and some soil organisms, and it was found that in all cases the paraflin was decomposed to a considerable extent, the amount being uninfluenced by the nature of the nitrogenous matter in the culture solution.

The nitrate ferment and the formation of physiological species, M. W. Beijerinck (K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdeel., 22 (1913-14), pt. 2. pp. 1163-1170; also in ditto, Proc. Sect. Sci., 16 (1913-14), pt. 2. pp. 1211-1217).—The author's studies have shown that the nitrate ferment, growing at the expense of organic food, soon loses its power of oxidizing nitrites to nitrates and changes into an apparently common saprophytic bacterium.

Summarizing the results of his investigations, it is said that the nitrate ferment represents a definite physiological species which may be kept constant in nearly pure inorganic nitrite solutions, but which, when better nourished with organic substances, passes into another physiological species which is much more constant. To the former the author gives the name Nitribacillus oligotrophus, and to the latter N. polytrophus. The first is a nitrate-forming organism while the second is not.

The study of plant enzyms, particularly with relation to oxidation, A. D. Hall, E. F. Armstrong, et al. (Abs. in Rpt. Brit. Assoc. Adv. Sci., 1913, pp. 143-145).—This summarizes the second report of the committee on the study of plant enzyms, and it lists related communications to the Royal Society, the most recent noted being apparently that of Keeble, Armstrong, and Jones (E. S. R., 30, p. 129).

It is stated that during the past year progress has been made in elucidating the part played by oxidizing catalysts in the production of plant pigments. Evidence accumulated favors the hypothesis that the soluble sap pigments of plants are formed by the oxidation of a colorless chromogen through the agency of an oxidase. The sap pigment may be reduced to the colorless chromogen by the agency of a reducing substance, as when the colored cell is stimulated by a hormone under conditions in which the amount of water present is at a minimum, the chromogen being reoxidized when excess of water is present in the system. Concentration of the cell sap thus shows close relation to the mechanism which controls the formation of flower color.

The work of Chodat (E. S. R., 30, p. 110) is also briefly discussed in this connection.

Some investigations in anthocyan formation, W. N. Jones (Abs. in Rpt. Brit. Assoc. Adv. Sci., 1913, p. 713).—This paper reviews some points thought to be of special interest considered in the communication above referred to.

It is believed that both a pigment producing mechanism and a reducing body are present in the petals, the amount of water in the cells determining which way the pigment reaction shall go. Reduction with decoloration occurs in 95 per cent alcohol, while in weak alcohol or water oxidation results in a production of pigment. Considerable quantities of reserve raw material are supposed to occur in some colored flowers which darken on fading, due, supposedly, to this reserve raw material coming into action under these circumstances.

Cytological studies on the formation of anthocyanin pigments, A. Guillermond (Rev. Gén. Bot., 25 bis (1914), pp. 295–337, pls. 3).—In continuation of previous studies (E. S. R., 30, p. 729), and considering the origin of anthocyanin pigments in buds, flowers, and other organs, also the formation of such pigments in leaves, the origin of the colorless phenol compounds, etc., the author states that in all cases examined the anthocyanic pigments formed resulted from mitochondrial activity, as did various colorless phenol compounds noted in most plants studied. Anthocyanin appears in general as pigment in the mitochondria, but the manner of its elaboration may be any one of several described.

Structural and functional homologies as noted between cells of vegetables and those of animals are also discussed. A large number of facts noted are said to favor the views of Combes (E. S. R., 31, p. 128) regarding the production of phenol compounds in plants as a normal and constant phenomenon and the production of anthocyanin as a modification thereof.

The question of the evolution and the physiological rôle of mitochondria, A. GUILLIERMOND (Rev. Gén. Bot., 26 (1914), Nos. 304, pp. 129-149, figs. 7; 305, pp. 182-208, figs. 9).—Summarizing the results of studies on the origin, development, chemical nature, intimate functions, and generalized character of mitochondria as noted in plants and animals, the author claims to have shown that mitochondria are concerned with the elaboration of the products of secretion which function chemically in the cell; that the function of the mitochondria is very general, probably the greater part of the products of secretion being elaborated therein; and that the chondriome is a constant and essential element of the functioning cell. A bibliography is appended.

Evolution of plastids and mitochondria in adult cells, A. GUILLIERMOND (Anat. Anz., 46 (1914), No. 20-21, pp. 566-574, figs. 16).—This is mainly a compact summary of results and conclusions already noted (see above).

Investigations in smoke injury. H. WISLICENUS (Samml. Abhandl. Abgase u. Rauchschäden, No. 10 (1914), pp. 168, pls. 4, figs. 19).—This is one of a series of reports under the editorship of the author on gas and smoke injury to plants, this number dealing systematically with external and internal disturbances produced by soot, smoke, and various acid fumes or gases during experiments or observations, which are discussed.

It is stated that carbon particles and insoluble salts are absolutely harmless to foliage in all its stages, but that leachings of soot, etc., as soluble salts, particularly sulphids and sulphites, cause a degree of injury to the foliage.

Pine and fir needles, while sensitive to sulphur dioxid, are not injured by sulphur trioxid in a dry medium, and in a damp atmosphere the injury is slow and somewhat limited, as is also the case of tender young foliage, which is more or less moist. Some fluorin compounds tested proved to be injurious. Light access, species, succulence, dilution with air, turgescence of guard cells, time of casting leaves, etc., modify the influence of gases on foliage. The time of greatest sensitivity appears not to be in winter or during the most abundant precipitation, but during the greatest activity of the leaves in summer.

FIELD CROPS.

Tillage and rotation experiments at Nephi, Utah, P. V. Cardon (U. S. Dept. Agr. Bul. 157 (1915), pp. 45, figs. 21).—This bulletin gives results of work carried on jointly by the Utah Station and this Department covering the period from 1908 to 1913, inclusive. See also a previous note (E. S. R., 30, p. 135). A description of the station and of the climatic conditions is included.

A summary of the tests that deal with time and depth of plowing, cultivation of fallow, seeding, cultivation and harvesting of the crop, frequency of cropping, and diversity of crops in rotation is given as follows: "The average results for five years, 1909 to 1913, inclusive, show that spring plowing was better than fall plowing for moisture conservation, in yield of grain, and in cost of producing the crop. Spring plowing gave an average yield of 18.5 bu, per acre, as compared with 16.8 bu, for fall plowing. Owing to this difference in yield and the lower cost of producing the crop, spring plowing gave a net acre profit of \$3.03 more than fall plowing.

"The results of five years show that there was no advantage in deep plowing or subsoiling over shallow plowing so far as moisture conservation is concerned. There was no material difference in the yields obtained from plats plowed at different depths, varying from 5 to 18 in. The highest average yield was obtained from plats plowed 10 in, deep, and the lowest average yield was from the plats subsoiled 18 in, deep, while the 5-in, plowing yielded higher than the 15-in, subsoiling.

"One year's results from a test of deep fall plowing and shallow spring plowing compared with shallow fall plowing and deep spring plowing show no difference in soil moisture and but slight difference in yield.

"The results of five years' experiments on fall-plowed fallow show that the moisture of the cultivated plats remained practically the same throughout the season, while that of the uncultivated plats rapidly declined, until by fall it was reduced to a comparatively low point. It is probable that weeds and volunteer grain were important factors in this loss of moisture. The average acre yield of the cultivated plats was 17 bu., as compared with 13 bu, on the uncultivated plats.

"The results of one season on spring-plowed fallow show no difference in the moisture content of the plats cultivated or not cultivated. The yields, 11.9 and 9.5 bu. per acre, favor the noncultivated plat.

"The results of 10 years show no correlation between the time of sowing winter wheat and the yield, but the best yields have usually been obtained from plats seeded between September 1 and October 15. There was no significant difference between the average moisture content of the plats for any one or for all years. The chief problem in the time-of-seeding tests of winter wheat now seems to be a mechanical one involving some improvement of the

machinery used in seeding. It is believed that this will obviate the necessity of waiting for rain before seeding, thus permitting early seeding, which seems desirable, and allowing the crop time enough to make a fair growth before the advent of winter. Late planting is often followed by much winterkilling, which completely offsets the value of any tillage method used in preparing the land and of the quantity of moisture stored in it.

"The average result of five years' tests shows no difference in the yields of winter wheat seeded at different depths. The yields were greatly influenced by conditions at seeding time. The ordinary drilling of winter wheat has given more profitable yields than broadcasting or cross-drilling.

"The results of three years' experiments show that winter wheat sown at the rate of 4 to 5 pk, per acre is more profitable than when sown at 3 pk, per acre, the rate ordinarily used on the dry lands of the Great Basin.

"The average yields of five years favor no spring cultivation of winter wheat. The noncultivated plats yielded 17.05 bu., as compared with 15.99 bu. from those cultivated. There was no apparent difference in the moisture content of the plats. A test made in the spring of 1913 showed that 11.54 per cent of the plants were killed by one harrowing. This loss offsets all benefits that might have come from harrowing.

"The results of four years favor harvesting when the grain is in the hard-dough stage.

"Where a good stand was obtained and little winterkilling followed, winter wheat after fallow yielded more than winter wheat on continuously cropped land. This depended largely upon the season, however, and the continuously cropped plat, owing to volunteer grain, yielded as well or better than other plats in the test in seasons of much winterkilling.

"The average acre yield of winter wheat for five years was less after fallow than after corn, potatoes, or peas."

[Field crop experiments], A. M. McOmie (Arizona 8ta. Rpt. 1913, pp. 243–250, fig. 1).—This reports work at the dry farms and the central station for 1913. At the Prescott dry farm Moqui Indian corn is noted as being inferior to Kafir corn in yield, and fallowed land proved more productive than that continuously cropped. Feterita, white mile maize, kaoliang, Sudan grass, durra, Canada field peas, tepary beans, and Grimm and Turkestan alfalfa are noted as being new introductions. Cultural trials with many varieties of spring and winter wheat, eats, barley, rye, spelt, emmer, and millet are noted. Turkey Red wheat planted about August 20 is the only winter cereal, it is stated, to mature at the experimental dry farms. It yielded from 10 to 12 bu, per acre. At Phoenix cultural trials of wheat, barley, eats, spelt, corn, sugar beets, sugar cane, grain sorghums, forage sorghums, shallu, potatoes, and tepary beans are noted.

Report of the work done at Holly Springs branch experiment station, 1913, C. T. Ames (Mississippi Sta. Bul. 165 (1914), pp. 13-21, 26, 32, figs. 4).— Tests with 26 varieties of corn gave yields that ranged from 30.5 to 57.8 bu. per acre; 28 varieties of cotton yielded from 352 to 671 lbs. per acre of lint cotton, or from 1.169 lbs. to 1.843 lbs. of seed cotton. Length of staple ranged from $\frac{1}{2}$ to $1\frac{\pi}{15}$ inches. Fertilizer tests indicated that the soil was deficient in both lime and phosphorus, as basic slag produced the best yields of lint cotton in fertilizer tests.

Some conclusions regarding the results of fertilizer tests with cotton covering a period from 1906 to 1913, inclusive, are given as follows:

"The use of both nitrogen and phosphorus, either alone or in combination, has given very satisfactory results.

ç

"Phosphorus hastens maturity. Valley land that is slow in maturing a crop can be very greatly benefited by its use.

"The use of potash, either alone or in combination with other elements, appears to be nunceessary in these soils.

"On thin uplands, the use of an equal mixture of acid phosphate and cottonseed meal, at the rate of 200 to 300 lbs, per acre, gives very satisfactory results, and has done so for the past 8 years. Two hundred lbs, of this mixture has increased the yield of seed cotton in many instances over 500 lbs, per year. On the more fertile soils the quantity of phosphorus may be increased to advantage.

"Acid phosphate alone, 200 to 300 lbs. per acre, can be used to profit after leguminous crops."

It is noted that in fertilizer and lime tests with cowpeas "one application of lime, at the rate of 2 tons of crushed stone or 1 ton of air-slaked lime per acre, will increase the yield of most legumes each year for several years. Lime wilt give better results when used under leguminous crops; however, on these soils almost any crop will respond to the use of lime. Ten tons of lime per acre for the contents of the first 7 in. of a soil is considered the minimum amount of lime for a maximum crop production, whereas these soils contain only about 4.500 lbs."

Yields of tests of 15 varieties of cowpeas and 6 varieties of soy beans are given.

Cultural methods are noted for alfalfa and crimson clover. Cultural methods for Lespedeza clover are described with reference to beneficial results obtained from the use of acid phosphate. Cultural and storage methods for use in the production of sweet potatoes are also given.

Report of the department of farm crops, I. L. Owen et al. (New Jersey Stas. Rpt. 1913, pp. 391-417, pl. 1, fig. 1).—In this report, continuing previous work (E. S. R., 30, p. 333) are given the costs of production of various field crops as derived from carefully kept records in 1913 on the station farms.

Records of a 9-acre field of alfalfa show the average cost of producing hay per acre to have been \$19.17, the average cost per ton. \$5.50, and the average yield per acre, 3.48 tons. Similar items of a 10-acre timothy field are given as \$34.05, \$8.58, and 2.98 tons; of a 14½-acre field of oats and pea hay, \$15.80, \$6.83, and 1.66 tons; of a 19-acre field of alfalfa, \$12.56, \$5.03, and 2.5 tons; of a 10-acre field of oat and pea hay, \$14.50, \$9.67, and 1.5 tons; of a 6-acre field of silage, \$28.88, \$3.32, and 8.68 tons; and of a 24-acre field of silage corn, \$29.36, \$3.73, and 7.87 tons.

The total cost of seeding a 14½-acre field of timothy and clover is given as \$23.10 per acre. The total labor cost of producing rye and vetch on 6 acres is given as \$98.93 and the total income as \$296.50. The average cost per acre of a 3½-acre field of rye straw and soy beans is given as \$6.15, the cost per ton as \$3.40, and the yield as 1.8 tons.

The total value of the crop from a 13-acre field of soy beans for seed is given as \$424 and the cost of production as \$207.32. The total cost of seeding a 10-acre field of alfalfa is given as \$168.42. Data are also recorded for buckwheat.

It is noted that the use of 16 per cent acid phosphate in mixing fertilizers in the place of 14 per cent acid phosphate caused the mixture to cake in the spreaders and made it necessary to distribute by hand.

[Field crops experiments, 1905], O. A. THOMPSON and J. H. SHEPPERD (North Dakota Sta., Rpt. Edgeley Substa. 1905, pp. 5-16, pl. 1).—These pages record results of variety tests with wheat, oats, barley, emmer, flax, corn, *

millet, and potatoes; cultural experiments with wheat, brome and slender wheat grass; and crop rotations carried on during 1905, in cooperation with this Department.

[Field crops experiments, 1906], O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpt. Edgeley Substa, 1906, pp. 12-26, pls, 3).—This reports the continuation of variety tests with wheat, oats, barley, emmer, einkorn, and potatoes, and tests of rotation, human conservation, and moisture conservation methods, carried on in cooperation with this Department in 1906.

[Field crops experiments, 1907], O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpt. Edgeley Substa, 1907, pp. 10-20, 23-37, pls. 6).—This outlines and describes cultural tests with cereals, slender wheat grass, brome grass, alfalfa, and clover, crop rotations, and moisture and humus conservation methods carried out in cooperation with this Department in 1907. Yields are given in variety tests of wheat, oats, barley, and rye.

[Field crops experiments, 1908–9], O. A. THOMPSON and J. H. SHEPPERD (North Dakota Sta., Rpt. Edgeley Substa, 1909, pp. 17–52).—This gives results of variety tests with wheat, oats, barley, rye, potatoes, rutabagas, carrots, mangels, sugar beets, corn, millet, rates of seeding millet, wheat, oats, and barley, and cultivation and variety tests with alfalfa, carried on in cooperation with this Department in 1908 and 1909.

[Field crops experiments, 1910], O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpt. Edgeley Substa. 1910, pp. 14-44, figs. 10).—This gives results of cultural tests with wheat, oats, barley, rye, brome grass, timothy, red, alsike, crimson, and white clover, bluegrass, Canada peas, and Dwarf Essex rape, and variety tests with wheat, oats, barley, potatoes, beets, sugar beets, mangels, carrots, rutabagas, corn, and alfalfa carried on in cooperation with this Department.

[Field crops experiments, 1911–12], O. A. THOMPSON and J. H. SHEPPERD (North Dakota Sta., Rpt. Edgeley Substa, 1912, pp. 8, 9, 12–42, 50).—This gives results of work with cultivation methods, cultural tests with wheat, oats, barley, rye, brome grass, slender wheat grass, potatoes, red, alsike, and crimson clover, timothy, Canada peas, and Dwarf Essex rape, a test of formaldehyde for potatoes, and variety tests with wheat, barley, oats, potatoes, beets, mangels, sugar beets, carrots, rutabagas, flax, corn, millet, and alfalfa carried on in cooperation with this Department.

[Field crops experiments, 1913], O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpt. Edgeley Substa. 1913, pp. 7-19).—This describes and gives results of some of the work carried on in cooperation with this Department.

In variety tests with wheat it is noted that the highest yields of grain produced in each class were 28.3 bu. for the durums, 30.6 bu. for the fifes, and 26.9 bu. per acre for the bluestems. Flax yielded from 52 to 54 bu. per acre.

The results of a test of rate of seeding with wheat, oats, and barley, ranging from 2 to 11 pk, per acre, covering the 5 years from 1908–1913, inclusive, showed that "in 1913 the heavier yields conform very closely to the heavier rates of seeding, while in other seasons, with the exception of oats, the heavier yields are associated with an intermediate rate." Dynamiting and subsoiling with wheat, oats, and barley gave doubtful results in 1912 and 1913.

The results of different methods of preparing land for cereals show, "in 1913, the early fall plowed land produced larger yields than any of the other methods employed. The spring plowed land comes second in the matter of production and the late fall plowed third. When the four-year average is considered, there appears to be no advantage obtained from packing the land either in the fall or in the spring. A comparison of the average yield of all

the fall methods of tillage with the average of all the spring methods shows a difference of 4.9 bu, per acre in favor of the latter."

Two cropping systems are outlined, one adapted to live stock farming and one to grain farming, and a fertilizer experiment is also outlined.

Average yields of wheat and oats grown with different cultural methods are given. The averages showed that "wheat on fallowed land stands first with a yield of 21.8 bu, per acre; second, on disked corn ground with a yield of 19.1 bu,; third, on all humus conservation plats with a yield of 18.8 bu; fourth, where green manure is plowed down with a yield of 18.1 bu,; fifth, on spring plowed land with a yield of 17.3 bu,; sixth, on fall plowed land with a yield of 16.6 bu, per acre. Comparing the average of the oat yields under the different treatments, we have the oats yielding first on the fallow land with a yield of 41.3 bu, per acre; second, on the green manure plats with a yield of 35.1 bu,; third, on the disked corn ground with a yield of 34.5 bu,; fourth, on spring plowed land with a yield of 34.1 bu,; tifth, on the all-humus conservation plats with a yield of 33.9 bu,; sixth, on the fall plowing with a yield of 31.4 bu, per acre."

[Field crops experiments, 1909], E. D. Stewart and J. H. Shepperd (North Dakota Sla., Rpt. Langdon Substa. 1909, pp. 7-11).—These pages report variety tests of wheat, outs, and barley, and cultural experiments with clover, flax, millet, peas and outs, and potatoes.

[Field crops experiments, 1910], E. D. Stewart and J. H. Shepperd (North Dakota Sta., Rpt. Langdon Substa. 1910, pp. 9-19, figs. 2).—These pages report crop rotation trials, variety tests with alfalfa, wheat, oats, and barley, and cultural experiments with brome grass, timothy, millet, corn, peas and oats. Canada peas, flax, rye, emmer, and potatoes.

As a result of the study of the root system of wheat it is stated that plants that were about 24 in, high had roots to the depth of 4 ft, 4 in., and that 75 per cent of the roots reached a depth of 2 ft, or more.

As a result of experimenting upon depth of plowing, it is stated that "close observation during the entire period of growth failed to show any difference except that there was slightly more straw on the spring plowed land. Fall plowing 5 to 6 in, deep gave a yield of 4.2 bu, per acre; spring plowing 5 to 6 in deep, 3.4 bu, per acre; and deep fall plowing 12 in, deep, 3.33 bu, per acre. The low yields are the result of the dry season."

[Field crops experiments, 1911], E. D. Stewart and J. H. Shepperd (North Dakota Sta., Rpt. Langdon Substa. 1911, pp. 9-29, figs. 3).—These pages report cultural tests with clover, alfalfa, corn, vetch, peas, timothy, millet, brome grass, redtop, western rye grass, flax, spring and winter rye, emmer, wheat, oats, and potatoes, and variety tests with alfalfa, corn, millet, wheat, oats, barley, and potatoes. Notes are given on a 5-year and 6-year crop rotation.

In regard to soil packing and fallowing for wheat, it is noted that "upon the 5 to 6-in, plowing-the ground not packed before seeding gave a yield of 1.07 bu, more than the packed ground. Upon the 12-in, plowing the ground packed gave a yield of 1.06 bu, more than the unpacked ground. Upon the spring plowing there was an increase of 1 bu, in yield on the packed land. . . . Where fallow ground is free from weeds a better yield can be obtained in this locality by the use of the ordinary peg-tooth harrow than where the ground is disked. Disking seems to loosen the ground more than is necessary to secure a good seed bed."

Experiments in different depths of plowing for spring wheat showed the yield of grain upon 5 to 6-in. fall plowing to be the best and that upon the spring plowing 3 to 4-in, was the poorest. On fall plowing to the depth of 12 in. "the straw grew taller and heavier and from the general appearance of the

field looked better during the growing season, yet when threshing was done the grade was considerably poorer, as the grain was shriveled and affected badly by rust."

With oats fall plowing to a depth of 5 to 6 in, gave a yield of 3.63 bu, more than upon the 12-in, fall plowing, and 11.75 bu, per acre more than upon the 3 to 4-in, spring plowing. Similar results are noted with barley.

[Field crops experiments, 1912], E. D. STEWART and J. H. SHEPPERD (North Dakota Sta., Rpt. Langdon Substa. 1912, pp. 7-32, figs. 4).—This gives results of variety tests with alfalfa, wheat, oats, barley, potatoes, and cultural trials with corn, clovers, peas peas and oats, vetch, timothy, millet, flax, winter and spring rye, enumer, winter wheat, oats, and potatoes, with notes upon the 5-year and a 6-year rotation.

In studying the root system of wheat grown on land fall plowed 3 to 4 in., 5 to 6 in., and 12 in. deep "it was found that 50 per cent of the roots grew to the depth of 2 ft. and over, and many roots were traced down to the depth of 6 ft. in the 3 different depths of plowing. It was also found that there was little or no difference in the root system in the different depths of plowing."

[Field crops experiments, 1913], E. D. STEWART and J. H. SHEPPERD (North Dakola Sta., Rpl. Langdon Substa. 1913, pp. 8-26, figs. 3).—This reports variety tests of wheat, oats, barley, and potatoes, and on cultural experiments with corn, peas, alfalfa, clover, flax, winter wheat, winter rye, early and late seeding of wheat, rates of seeding wheat upon corn ground and upon timothy sod, methods of treating corn stubble to be sowed to wheat, different rates of seeding oats and barley, and different depths of plowing for wheat, oats, barley, timothy, and corn, and notes on rotations.

Summary of results [in] field husbandry, 1913, O. C. White et al. (Canada Expt. Farms Bul. 75 (1914), pp. 43).—This bulletin gives in a summarized form the more important of the season's results secured from crop production and field experimental work as carried on at the several experimental farms in continuation of previous work (E. S. R., 32, p. 431).

Numerous crop rotations are described. The costs of operations per acre of the several rotations at the central station for 1913 are given as ranging from \$17.08 to \$21.83, and the average profits for eight years preceding 1912 as ranging from \$8.15 to \$10.08 per acre. The cost of production for oats is given as 30.8 cts. per bushel, for hay (first year) \$4.06 per ton, hay (second year) \$4.12 per ton, turnips \$1.86 per ton, and corn \$1.72 per ton.

In regard to the use of barnyard manure and commercial fertilizers in these rotations, it is noted that "the five years' results... show a distinct advantage of barnyard manure alone over commercial fertilizer alone for this soil, but point to the possibility of combining the two to good advantage when barnyard manure is scarce or high in price."

The eradication of couch (twitch or quack) grass by the use of the spring tooth and smoothing harrows is noted.

The cost of production per bushel of the rotation crops at Nappan, Nova Scotia, are given as follows: Turnips 5.94 cts., mangels 7.68 cts., potatoes 13.13 cts., oats 28.9 cts., wheat 48.9 cts., barley 40.8 cts., and silage corn \$3.10 per ton.

At Cap Rouge, Quebec, the results of different rates of seeding corn (Long-fellow) for silage during three years are given as follows: In rows 8 by 42 in., 9 tons 1.094 lbs. per acre; 8 by 48 in., 8 tons 1.754 lbs.; in hills 36 by 36 in., 5 tons 1.398 lbs.; and 42 by 42 in., 5 tons 1.364 lbs.

At Indian Head, Saskatchewan, the profit per acre on land in a 3-year rotation of summer fallow, wheat, and wheat is given as \$9.61; of a 6-year rotation of summer fallow, wheat, wheat, oats (seeded down with western rye

grass and alfalfa), hay, and pasture \$12.08; of an 8-year rotation of summer fallow, wheat, wheat, summer fallow, corn, barley (seeded down with western rye grass and alfalfa), hay, and pasture \$8.32; and of a 9-year rotation of summer fallow, roots, wheat, oats, summer fallow, wheat, oats (seeded down with western rye grass and alfalfa), hay, and pasture \$9.12.

In regard to a 3-, 6-, 8-, and 9-year rotation at Rosthern, Saskatchewan, it is noted that "land worked under a rotation including grains and hay gives a greater profit per acre than where wheat alone is grown, and this is emphasized in a season of early frosts; that a hoed crop in the rotation increases the cost of operation per acre, but very much more increases the profit per acre as well as the yield of the succeeding grain crops."

In studying the relative value of summer fallow manured, summer fallow without manure, green crops of peas, and vetches plowed under it is noted that the plowing under of a green crop evidently left the ground too dry for any great benefit to be derived by the crop of the succeeding year, but showed an advantage over bare fallow in the second succeeding crop.

The yields of hay in 1913 at Scott, Saskatchewan, as results of various methods of seeding 10 lbs, each of western rye grass and red clover seed per acre, are given as follows; With wheat after summer fallow, 2 tons 400 lbs.; alone after summer fallow, 2 tons 1,200 lbs.; with wheat after roots, 2 tons 800 lbs.; alone after roots, 2 tons 680 lbs.; with wheat after wheat, 1 ton 1,240 lbs.; alone after wheat, 1 ton 1,160 lbs.; with oats after wheat, 1,720 lbs.; alone after wheat on manured land, 1 ton 80 lbs.; with wheat after two successive crops of wheat, 1 ton 820 lbs.; alone after oats preceded by wheat, 1 ton 400 lbs.; with wheat after wheat preceded by a hoed crop, 1 ton 1,860 lbs.

In regard to the experimental work at Lethbridge, Alberta, it is noted that "on the dry land the yields of hay were very light. Brome grass produced only 1,580 lbs., and western rye grass 1,160 lbs. per acre. Alfalfa sown broadcast yielded only 1,481 lbs. per acre whereas alfalfa sown in rows yielded about double this amount. . . .

"Wheat following corn yielded as well as wheat after summer fallow, and much better than wheat following turnips. The latter difference is no doubt due to the fact that the roots made considerable growth in the fall, thereby using up moisture, whereas the corn ceased growth with the first frost. A good profit was obtained from alfalfa seed when the crop was planted in rows and intertilled. Heavy yields of oats and peas, grown for feed, were obtained when sown on summer fallow. With irrigation, the yield of spring wheat was over 52 bu. per acre, following potatoes. With irrigation, potatoes planted on alfalfa sod gave a yield of 635 bu. 30 lbs. per acre. . . .

"Our results to date indicate the following rates of seed per acre to be the best: Winter wheat, nonirrigated, 60 lbs.; spring wheat, nonirrigated, 75 lbs.; oats, nonirrigated, 60 to 75 lbs.; barley, nonirrigated, 75 to 90 lbs.; spring wheat, irrigated, 90 to 105 lbs.; and oats, irrigated, 75 to 90 lbs."

At Lacombe, Alberta, trials of graded seed showed that "wheat fanned three times, under strong wind, yielded 35 bu, 11 lbs. per acre, wheat fanned once yielded 26 bu, 50 lbs., and wheat not fanned, 24 bu....

"The deep working of the land in the summer fallow year did not appear to give any special results on the first succeeding crop (wheat) but influenced favorably the second crop (oats). In the breaking out of sod, plowing at a depth of 5 in, gave better results than at 3 or 4 in. This practice also proved superior, this year, to breaking sod 3 in, and plowing the wheat stubble 6 in, for the following oat crop."

In summer fallow treatment it is noted that "it is of advantage to plow summer fallow but once, that deep plowing gives better results than shallow plowing, and that working or plowing the stubble land in the fall previous to the summer fallow does not always result in increased yields."

Notes are given on the first year's trials at Agassiz, British Columbia, with nitrate of soda v, nitrate of lime for mangels, commercial fertilizer alone v, commercial fertilizer together with barnyard manure, spring application v, winter application of fresh manure, and winter application of manure (fresh) v, spring application (stack).

Summary of results [with] forage plants, 1913, M. O. Malte et al. (Canada Expt. Farms Bul. 76 (1914), pp. 32).—This bulletin gives summarized results of the more important experiments with forage crops conducted at the several experimental farms during 1913. Brief notes are presented regarding variety tests of turnips, mangels, carrots, corn, and sugar beets, and preliminary work in breeding alfalfa, clovers, timothy, orchard grass, western rye grass, and wild grasses, etc.

[Effect of frost on forage and other plants], J. J. THORNBER (Arizona Sta. Rpt. 1913, pp. 251-255).—This notes the serious injury to the native and cultivated forage and other plants caused by the unusually low temperature of the winter of 1912-13.

[Alfalfa and wheat breeding experiments], G. F. Freeman and J. C. T. Uphof (Arizona Sta. Rpt. 1913, pp. 257-261, 263-265).—This gives further observations regarding investigations with alfalfa (E. S. R., 31, p. 629). It is noted that the studies of 144 pure races of alfalfa "give promise of affording (a) pure races of alfalfa of the Peruvian type, which heretofore has shown itself so productive in mass cultures; (b) improved strains of the rapidly growing Mediterranean alfalfa for use in short rotations; and (c) strains high in both leafiness and productivity, which will be of value to the dairy industry."

The points involved in a study to increase the water efficiency of alfalfa are noted as being rapidity of growth, rate of transpiration per unit of surface exposed, ratio of transpiring surface to total dry matter produced, the distribution and length of root system, osmotic density of cell sap, ability of the plant to become dormant in seasons of water famine. The study has thus far shown that some strains will regularly mature a crop from five to seven days earlier than others under the same conditions; that certain strains or varieties under identical conditions regularly give off more water than others per unit of green weight or of leaf surface exposed; that the percentage of leaves in different pure races varies widely; that the rate of growth does not depend upon the amount of water transpired; that there is usually a minus correlation between yield and percentage of leaves; and that varieties of alfalfa differ markedly in their ability to become more or less dormant during seasons of extreme heat or water famine.

Breeding and selection work in progress with Algerian and domestic hard wheat varieties is briefly described. Yields ranging from 21 to 67 bu. per acre are recorded.

Alfalfa in the Southwest, G. F. Freeman (Arizona Sta. Bul. 73 (1914), pp. 233-320, pls. 2, figs. 19).—This bulletin contains information gathered from several sources upon the culture, harvesting, storage, uses, and enemies of alfalfa, with special reference to Arizona conditions.

The discussion includes acid and alkaline soils, methods of irrigation, the alfalfa caterpillar, green alfalfa hopper, grasshoppers, harvester ant, variegated cutworm, alfalfa weevil, brown root rot, leaf spot, rust, downy mildew,

crown gall, Phonia disease, stem rot, dodder, and such weeds as Johnson grass, Bermuda grass, wall barley, water grasses, dock and canaigre, pigweed, sour clover, and bur clover.

The bulletin terminates in tables taken from several sources, showing the composition of alfalfa and the commercial grades of the hay.

Hairy vetch for the cotton belt, C. V. PIPER (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 15, pp. 4, fig. 1).—Brief notes on methods of production.

Winter oats in the cotton belt, C. W. WARBURTON (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Nov. 21, pp. 4).—Brief notes on methods of production.

Rape as a forage crop in the cotton belt, C. V. Piper (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 15, pp. 3).—Brief notes on methods of production and uses.

Rye in the cotton belt, C. E. LEIGHTY (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 2, pp. 4).—Brief notes on methods of production.

Sorghum for forage in the cotton belt, H. N. VINALL (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 23, pp. 4).—Brief notes on methods of production and uses of sorghum and Sudan grass.

Soy beans in the cotton belt, W. J. Morse (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1915, Jan. 12, pp. 6).—This discusses methods of production and uses.

Trials with sweet clover as a field crop in South Dakota, A. N. Hume and M. Champlin (South Dakota Sta. Bul. 151 (1914), pp. 3-20, figs. 6).—This bulletin gives a brief description of sweet clover, the possibilities in its use, and results of tests in South Dakota. Sweet clover sown in corn in August is noted as yielding 3.6 tons of hay in two cuttings the next year and 0.8 tons of hay and a seed crop of 5.9 bu, per acre the second year. Sweet clover sown in April in fall wheat is noted as being successful.

Letters are quoted from farmers of South Dakota who have produced sweet clover successfully. Data of rainfall for varying periods from 1905 for four localities of the State are given.

Winter wheat in the cotton belt, C. E. LEIGHTY (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Nov. 21, pp. 6).—Brief notes on methods of production.

Winter wheat, A. Atkinson and J. B. Nelson (Montana Sta. Bul. 100 (1914), pp. 147-160, figs. 4).—This bulletin notes Turkey Red and Kharkov varieties of wheat as being most commonly grown in Montana. In several years' tests on demonstration farms the former averaged 25.6 bu, per acre. As a 5-year average at the Fergus County substation the Kharkov variety is noted as yielding 35.2 bu, and Turkey red 32.8 bu, per acre. In rate-of-seeding tests, from 3 to 4 pk, are noted as giving the best results. The time-of-seeding tests showed that August and early September seedings were the most satisfactory.

"Harrowing winter wheat in the spring reduced the yield in nearly every case. Rolling in the spring increased the yield in the tests conducted. Spring harrowing of winter wheat reduced the stand 19.4 per cent when compared with the wheat not harrowed. The unharrowed wheat produced an average of 4.5 heads per plant and the harrowed wheat 4.3 heads per plant. Wheat drilled in between the rows of standing corn gave a fair yield, and it is probable that this method of seeding will be very generally adopted as the area devoted to corngrowing increases."

The continuous growing of wheat and rye, 1913, J. G. LIPMAN ET AL. (New Jersey Stas. Bul. 268 (1914), pp. 19-21, pl. 1: Rpt. 1913, pp. 471-473, pl. 1).— This reports the continuation of work previously noted (E. S. R., 30, p. 325). The plan of the experiment has not been modified, and the results are similar to those of 1911 and 1912, showing that even a leguminous crop which has not attained full development may add enough humus and nitrogen to the soil to

more than double the yield as compared with plats which have grown no legume.

Permanent pastures for the cotton belt, L. Carrier (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 23, pp. 4).—Brief notes on the methods of production of Bermuda grass, Lespedeza, bur, and white clover, carpet grass, Italian rye grass, redtop, orchard grass, and hairy vetch.

Report of the seed analyst, J. P. Helyar and R. Schmidt (New Jersey Stas. Rpl. 1913, pp. 369-375).—This contains brief notes on scope of the work, equipment of the laboratory, and data showing results of the analyses of 486 samples of seeds.

HORTICULTURE.

Report of the horticulturist, M. A. Blake, A. J. Farley, and C. H. Connors (New Jersey Stas, Rpt. 1913, pp. 89-173, pls. 14).—Data are given on a survey of the peach industry within a radius of six miles of the Vineland experiment orchard (E. S. R., 30, p. 344). The influence of the control of the brown rot and peach scab and the successful shipping of the first crop of peaches from the experimental orchard in 1910 appears to have greatly stimulated the peach industry as a whole, for the total plantings for the last three years are in excess of 76,000 trees as compared with about 20,000 trees for the previous three years. Most of the orchards are receiving good care in cultivation and fertilization. Of the varieties planted the Elberta ranks first in number, followed by Carman. Champion, Belle of Georgia, and Ray. A brief account is given of the work of the past season in the Vineland orchard, including an outline of spraying practice. Orchard heaters were tested during the blooming period and the temperatures kept above freezing, but high winds and wet weather greatly interfered with pollination.

During the spring of 1913 a study was made by C. Miller of the viability of the pollen of the peach, nectarine, currant, and gooseberry. The results and observations of this study are briefly recorded here. A preliminary test of various solutions in which to germinate pollen resulted in the selection of a 20 per cent sugar and gelatin solution, and also a 20 per cent sugar solution, the former being most satisfactory for the germination of peach pollen.

A study of the viability was made with pollen gathered fresh from the trees just previous to each test. Ripe pollen which would germinate was found upon seven varieties of peaches and three of nectarines from April 9 to 21, or a period of thirteen days. There were many periods of wet weather during the blooming period, and it was noted that ripe, yellow pollen grains upon the anthers turned to a grayish white and had a leached appearance following such wet conditions. All such grains failed to germinate when tested in the laboratory. Some varieties were found to be more capable of germinating in dilute sugar solutions than others. It is suggested that such varieties should be at an advantage during wet blooming periods.

Viability tests were also made of peach and nectarine pollen taken from blooming twigs kept in the laboratory. Very little pollen was in condition for germination until April 7. Fairly constant results were secured with most varieties from April 9 to 17, when a rapid falling off in the ability of the pollen to germinate occurred with two exceptions—Belle of Georgia pollen gave a 49 per cent germination on April 26, having yielded pollen capable of germinating over a period of 22 days, and Carman gave a 43 per cent germination upon April 22.

Pollen secured from Maule Early twigs germinated in sugar solution for a period of only nine days. Some pollen was collected and placed in a bottle,

which was sealed and placed upon a shelf in the laboratory. Such pollen gave a good percentage of germination ten days after pollen of the same variety had failed to germinate when kept exposed to the air.

In addition to the considerable difference in varieties as to the length of time the pollen will remain viable, the authors conclude that there is variation between the pollen from trees of the same variety occasioned by factors which affect the development of the flowers.

Somewhat similar viability tests were conducted with the pollen of the goose-berry and currant. The pollen of three varieties of gooseberries commenced to germinate well on April 21 and continued to do so for a period of nine days. A small percentage of pollen showed its ability to germinate as late as May 3. The results of the tests with currants show that ripe, viable pollen occurred upon the plants from about April 21 to May 12 to 14, depending upon the variety, or a period of from 21 to 23 days.

Some crossing work was also attempted with gooseberries and currants. The number of crosses was small, but the results apparently indicate that the Wilder, Pomona, and Red Cross varieties of currants are self-fertile.

Tables are given showing the blooming dates for the seasons of 1912 and 1913 of the various kinds and varieties of fruits grown on the college farm, together with a discussion of weather conditions at the actual blooming period of certain varieties of fruits and the effect of the weather upon the flowers and fruit.

The results of dynamiting for tree planting, based upon all of the tests made at the station during the past two years, indicate that there is a greater development of branch and twig at the close of the first season's growth for peaches, but only a slightly greater development for apples where the trees are planted with dynamite. See also a previous note (E. S. R., 29, p. 339). This development has not been accompanied by a corresponding increase in the circumference of the trunks. Both apple and peach trees planted with dynamite have developed a deeper and stronger root system than trees planted in the usual manner. In all the tests made, both with apples and peaches, the percentage of trees living through the first season was practically the same, whether dynamite was used or not. This is attributed to a previous thorough preparation of the soil before planting. The results of the tests as a whole indicate thus far that the advantage in twig growth the first season shown by the trees planted by the use of dynamite is not maintained the succeeding year.

Results are given of experiments conducted with American Beauty roses in a commercial greenhouse during the seasons of 1910 and 1911. They indicate that the American Beauty rose is markedly affected by the amount of light which it receives in the greenhouse. All other conditions being equal the monthly yields of this rose are reduced during the dull months of the year. Experiments show that even in modern well-lighted rose houses plants near the south side of a bench are more productive than plants near the north side. The general vigor of the plants is not greatly reduced during the dull period. Individual plants favored by extra light are more productive even in bright months, such as May and June. Too close planting is likely to result in low yields from the less favored plants.

A paper dealing with a study made by C. H. Connors relative to the multiplication of floral parts in the carnation, previously noted (E. S. R., 30, p. 644), is here given,

Soil, temperature, and moisture studies with carnation and rose soils were conducted in the station greenhouse by J. S. Obecny, largely with a view to determining the variable factors to be considered in investigations with plants under greenhouse conditions. In the data and observations recorded, the follow-

ing phases are considered: The relation of fineness of soil division, various kinds of organic matter, sand, and bench construction to maximum moisture; the relation of age to the water-holding capacity of soils; and the relation of maximum moisture to optimum moisture. In the discussion of soil temperatures, consideration is given to the relation of air temperature to soil temperature, the effect of location of heating pipes on soil temperatures, the effects of sun, ventilation, and direction of wind on soil temperatures, and the relation of moisture to soil temperatures.

The results of greenhouse fumigation with potassium cyanid are reported. Fifteen fumigations were conducted in rose and carnation houses with 98 per cent potassium cyanid, used at the rate of five-eighths of an ounce to 1,000 cu. ft. of greenhouse space. The temperatures inside the rose houses varied from 62 to 80° F., inside the carnation houses from 54 to 60° F., and the length of time for each fumigation varied from 16 to 17 minutes. The result in the destruction of aphis in the rose houses were good in all cases but in some instances slight injury to the foliage resulted. Fumigations at the above noted strength and duration failed to destroy many of the aphis in the carnation houses. Subsequent experiments indicated that fumigations for the destruction of green aphis are not likely to prove successful where the temperature of the greenhouse is 60° F, or below, and where the amount of cyanid used is at the rate of three-fourths of an ounce to 1,000 cu. ft. of space unless the time of fumigation is prolonged to exceed 30 minutes, and even this may not bring success.

A peculiar form of injury to carnations was observed after one fumigation. This appeared in the form of a light ring or band upon the calyx. The injury occurred upon small immature buds and also upon buds that were opening. It was so slight, however, that it did not appear to affect the quality of the flower. Observations upon a disease of carnations are noted on page 549.

In order to control red spider upon American Beauty roses, a spray, consisting of a mixture of fish-oil soap and blackleaf 40, was used. This was used at the rate of 130 gm, of fish-oil soap and 3 gal, of water to which was added 1 fluid ounce of blackleaf 40 to 300 fluid ounces of water. It was observed that some of the foliage was burned by the application. Subsequent spraying with the fish-oil soap alone caused the same injury, hence it is concluded that the tobacco extract did not cause the damage.

In view of the considerable damage done by insects and diseases of the apple in the State during the past senson, an outline of the spraying treatment applied to the college farm orchard is here given, including the special treatment for the control of green aphis or plant lice upon apples.

[Report of botanical investigations], B. D. Halsted et al. (New Jersey Stas. Rpt. 1913, pp. 537-588, pls. 12).—Inheritance studies of various crosses of sweet, pop, and flint varieties of corn and of peppers (E. S. R., 30, p. 342) were continued in 1913. Starchy and sweet grains from different corn crosses were grown and data are given with reference to the transmission of such characters as length of stalks, number and weight of ears, and color and texture of the grains. F₃ grains of Country Gentleman crossed with Squaw were selected from 10, 12, 14, and 16 rowed ears as well as from zigzag ears. There was some evidence of inheritance of row character to the extent that the greater the number of rows in the parent ear the greater the tendency to produce many-rowed and zigzag ears. The proportion of zigzag ears was greatest when taken from a zigzag parent ear. The 12-rowed ear was dominant in all of the plantings.

A test was also made of the viability and vigor of starchy and sweet grains selected from the same set of ears. The results show that when the starchy grains are heavier and larger but without any marked difference in specific

gravity, the viability of the starchy grains is very uniformly higher, as are also the weights of the seedlings. Plantings were made at depths of 1, 2, and 3 in. The mesocotyl for the starchy grains was shorter for the 1-in. plantings and nearly the same for the 2 and 3 in, depths. The range of variation in length of the mesocotyl was usually less with the starchy than with the sweet grains.

In the work with peppers some 14,000 plants were grown, a large proportion of which were of the second generation. Tabular data are given for the fruit of a large number of these crosses showing average weight, volume, length, and breadth, as well as the range in length and breadth, the average number of locules, and the range in number of locules. Data are also given showing the averages of weights, lengths, and breadths of F_1 and F_2 fruits and the relation of number of locules to size in F2 fruits. Observations on pendency and uprightness in pepper fruits suggest that the position of the fruits follows the ordinary Mendelian segregation, with pendency dominant. With reference to the inheritance of deciduousness of pepper fruits it appears that deciduousness is dominant to persistency in F₁, the latter appearing again as a recessive in F₂. Observations on the inheritance of shape in the calyx for a number of crosses indicate that there is no well-defined segregation in the form of the calyx. Some general observations are given on pepper crosses with reference to spotted leaved, sterile, and dull fruited plants, plants with peculiar maturing colorations and with yellow foliage, and the best crosses commercially considered.

Report of progress, B. H. A. Groth (New Jersey Stas. Rpt. 1913, pp. 615-621, pls. 5).—In continuation of previous work (E. S. R., 30, p. 343), about 4,500 plants of the third generation of tomato crosses were grown in 1913. All of the lots had been selected from F₂ generation plants in order to shed further light on the heredity of characters of size and shape. The results in detail are to appear in a subsequent bulletin.

The work has not demonstrated thus far a strict Mendelian inheritance of size or shape characters. It has been found that the size characters of the fruits behave differently in the first generation from those of the leaves and stems. In certain crosses the greater vigor of the F_1 plants is lacking in all of the F_2 plants, while in other crosses it is maintained even in the F_3 plants. The average fruit size of a F_2 generation agrees fairly well with the average of the parent F_1 generation, except in the crosses with long fruits. In one "Pear" cross the vegetative parts of F_2 plants averaged smaller than those of F_1 while the fruits averaged much larger.

A strong correlation has been found to exist between shape and the larger number of locules in the fruit. In crosses of flat fruits with long ones there was a correlation between absolute size and shape. Likewise the slaty foliage color of "Peach" tomatoes and the dull surface of their fruit skins were correlated with flabby interior of the fruit and invariably accompanied by a poor filling of the locules, although this latter condition may exist independently of the other characters.

In some crosses it was easy to reproduce the absolute size of the parent fruits in F_2 and F_3 ; in others the fruits of the larger parent were not even approximated. Some of the F_3 lots of "Ponderosa" crosses bred true to a very light-green foliage color. One F_3 block of "Peach-Pear" crosses bred true to a pear shape of greater relative and absolute length than was found in either parent. Other F_3 blocks bred true to a factor for simultaneous ripening and cessation of flowering after this ripening period. Among the F_3 lots of "Currant" crosses some seemed to be heterozygous and some homozygous for an exceedingly tough

skin. In the Ponderosa \times Dwarf Stone crosses of both F_2 and F_3 isolated plants were found that surpassed any tomato known to be on the market in solidity of the interior combined with absence of core and smooth round shape.

Further selections of many-celled and 2-celled fruits in the prairie berry failed to show any connection between cell number in the parent and in the progeny. The prairie berry has been crossed with another variety of the black nightshade with the view of determining whether fasciated fruit could be isolated by crossing in this manner. Several F₂ plants of this cross have appeared in which the fluctuation in cell number of the prairie berry reappears but not in which fasciated fruits are the rule. Certain dwarf plants were secured from this cross, whereas no dwarf plants have thus far appeared in the breeding work with prairie berries.

The sap circulation experiment outlined in the previous report (E. S. R., 30, p. 343) gave inconclusive results and is to be repeated under more favorable circumstances.

The study of the effect of various chemicals on plants was continued. The tests involved the effects of equal amounts of NO₅, SO₅, PO₄, and Cl in the form of similar sodium, potassium, calcium, and ammonium salts. Buckwheat was used in one set of pots and buckwheat and sweet potato vine in another set. The results thus far here briefly studied show that the untreated pots and those containing chemicals soluble with difficulty matured first and kept ahead in growth. Those receiving the smaller excesses of nitrogen and phosphate salts developed much slower than the controls but began to branch out profusely later, and when the controls were already fully matured and dead the nitrogen plants especially became fully as large, more branched, and bloomed profusely. It is possible to distinguish between the symptoms of plants suffering from the lack of a salt and those suffering from an excess, and between plants suffering from equal doses of different salts, but thus far it has not been possible to tell whether a plant suffered from a small excess of one salt or from a large excess of another.

A study of inheritance in garden plants, E. J. Owen (New Jersey Stas. Rpt. 1913, pp. 622-629, pl. 1).—In continuation of previous work (E. S. R., 30, p. 343) character transmission in a number of bean crosses is discussed and the average plant growth and yield of fruit in eggplant and okra crosses is given. Data are also given on limitation studies with beans and tomatoes, together with a brief note on tomato novelties. The limitation studies continue to show that the restriction of fruit bearing to one fruit in the parent plant leads to a greater development of blossoms in the progeny.

[Variety tests at the Edgeley substation], O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpt. Edgeley Substa. 1912, pp. 42-44).—For several years a number of varieties of apples, plums, cherries, gooseberries, currants, and strawberries have been tested with reference to their general adaptability to soil and climatic conditions at the substation. The varieties under observation are here classified with reference to their degree of hardiness. Trials made with different classes of vegetables show that it is possible to grow almost anything in the vegetable line at Edgeley.

Report of the horticulturist, C. C. Newman (South Carolina Sta. Rpt. 1914, pp. 16-19).—A brief progress report on the work of the horticultural division.

As a result of the apple breeding work started by the station some ten years ago, more than 500 crosses have been made. Only a few of these trees have fruited thus far and only two crosses have shown any exceptionally desirable characteristics. One of these, Albemarle Pippin crossed on Golden Russet, fruited the past season and appears to be of promise for the Piedmont region of the South because it ripens very late in the season and is a splendid keeper.

A description is given of a seedling pear of the russet type which has fruited at the station for the past two seasons and promises to be one of the most valuable pears for the entire South.

The Chinese wood oil tree, which was received from the U.S. Department of Agriculture for testing purposes, fruited heavily during the past season and gives promise of being adapted for successful growth at the station.

Experiments have been conducted during the past three years to determine the best variety of Irish potato for a second crop. Of the varieties tested Lookout Mountain has given the best results. The tubers of this variety sprout very readily and an average stand of over 90 per cent can be secured, as compared with 40 to 60 per cent for other varieties. The tubers keep perfectly from November until planting time in July under ordinary storage.

A study of methods of propagating the scuppernong and other varieties of Rotundifolia grapes indicates that the best time for making cuttings of the Rotundifolia grapes is during the months of May, June, and July. Only about 15 per cent of dormant cuttings placed in the open ground during the fall will root. The green wood cuttings appeared to root much more readily than cuttings taken later on in the season.

Horticultural experiments at the San Antonio field station, southern Texas, S. H. Hastings and R. E. Blair (U. S. Dept. Agr. Bul. 162 (1915), pp. 26, figs. 8).—This bulletin gives the results of experiments conducted for a number of years (E. S. R., 32, p. 337) to determine the varieties of fruits best adapted to conditions in the San Antonio region, and also to find out what varieties or species may be used as stocks upon which desirable but less resistant varieties may be grafted. Suggestions are also given on cultural methods best adapted to the region.

The tests as a whole show that the climate is too severe for such fruits as oranges and olives and too mild for apples and cherries. Among the fruits which are considered more or less promising for the region are varieties of the South China race of peaches, a number of the American and Japanese plums, pears on the higher lands, figs, persimmons, pomegranates, jujubes, and dewberries. Cultivated varieties of grapes related to the native grapes may be grown but are not valuable as table grapes. The Rusk variety of citrange was hardy and made good growth.

Of the nuts tested, the native pecan does well as a lowland tree but has given poor results even under irrigation on the uplands. The Persian walnut makes good growth when worked on either Juglans vupestris or J. nigra. Almonds flowered so early as to be injured by frost. Pistache trees were found to be quite susceptible to root rot. Canada peas have proved to be the most satisfactory green manure crop.

Division of horticulture.—Summary of results, 1913, W. T. Macoun et al. (Canada Expt. Farms Bul. 77 (1914), pp. 68).—This comprises a summary of results secured in 1913 in the breeding and cultural experiments with fruits, vegetables, forest and ornamental trees, and herbaceous plants conducted at the Central Farm. Ottawa, and at the various branch experimental farms and stations in Canada. The details of the work are to appear as usual in the annual report at a later date.

As result of long continued variety tests at Ottawa a list of the varieties of fruits is here given that are considered best for eastern and central Ontario and a considerable portion of the Province of Quebec, together with a list of the 25 best seedling apples originated at the farm. Since 1903 some 1,214 new varieties have been fruited.

Tent caterpillars were successfully controlled in the orchard by using arsenate of lead with lime-sulphur and with Bordeaux. In cases where masses of caterpillars were found on ornamentals and on individual trees a dust composed of pyrethrum and 4 parts of cheap flour as well as an emulsion made up of 8 oz, of flour and 1 qt, kerosene to 2 gal, of water were found to kill the caterpillars quickly by contact.

The work at the branch stations and farms consisted largely of variety tests. At the Kentville substation, Nova Scotia, W. S. Blair in charge, tests were made of Bordeaux r, lime-sulphur in controlling apple scab. Lime-sulphur was practically as effective as Bordeaux in controlling the scab and caused much less russeting of the fruit than Bordeaux. The 3:3:40 Bordeaux appeared to russet the fruit as much as the 4:4:40. Arsenate of lead used alone showed no fungicidal value.

Plant introduction and acclimatization, J. J. Thornber (Arizona Sta. Rpt. 1913, pp. 255, 256).—A brief statement of proposed work with native walnuts, elderberries, and currants, together with a list of native hardy ornamentals growing at the station grounds.

[Bean breeding investigations], G. F. Freeman and J. C. T. Uphof (Arizona Sta. Rpl. 1913, pp. 261-263).—The work with beans has been confined to the selective breeding of the white tepary and to certain studies of inheritance among hybrids and pure races of both beans and teparies. Continued efforts to cross the bean upon the tepary and also the tepary and the Lima bean have resulted negatively. A few pods of the tepary-Lima cross were set but all failed to mature seed.

A small plat sown broadcast to tepary beans, at the rate of 60 lbs. per acre, gave an estimated yield of about 31 tons of air-dry hay per acre.

In the tepary breeding plat, 105 plant rows were grown, each row being from the seed of a single plant selection of the previous year. A marked contrast was observed between different rows as to the relative proportion of vine and seed, time of maturity, habit of growth, and productivity. The average for all races was 35 per cent of dry cleaned seed.

Phosphate for spinach, T. C. Johnson (Virginia Truck Sta. Bul. 11 (1914), pp. 269-276).—A previous bulletin gave in detail the plan of a combined fertilizer, soil management, and cropping system experiment with truck crops started by the station in 1908. The effect of various treatments, as measured by a crop of kale grown during the season of 1912-13, was also shown (E. S. R., 30, p. 532). In the present bulletin the author presents data for the 1913-14 kale crop and also shows the effect of various treatments as measured by crops of spinach during the season 1913-14. Although no conclusions are drawn from the work, thus far the results indicate that spinach requires a considerably larger quantity of phosphoric acid than is contained in the ordinary fertilizers used.

An apple orchard survey of Mills County, L. Greene (*lowa Sta. Bul. 153* (1914), pp. 252-316, figs. 35).—This bulletin gives the results of a survey conducted in 1911-12 relative to the conditions and methods of management of the apple orchards in Mills County. Iowa. With results of this survey as a basis, suggestions are given relative to the renovation and care of apple orchards.

The orchard area in Mills County is about 3.000 acres, and the average age of the trees 19 years. The average planting distance was found to be 22 by 22 ft. Although no data were secured with reference to the effect of planting distance on yield, observations on the general conditions of the orchards indicate that the trees were planted too close for the best results. Eighty-two per

FORESTRY. 541

cent of the orchards were in sod, 8 per cent in sod mulch; 12.6 per cent was manured; and 11 per cent was partially tilled. The orchards return an average annual net profit per acre as follows; Sod, \$86.50; sod and manure, \$140.83; sod mulch and partial tillage, \$115. Orchards which were pruned annually yielded a much greater net profit than those pruned less frequently or not at all. The practice of spraying was not general in the county but the net returns from the orchards which were sprayed were greater than those from unsprayed orchards.

The most important diseases found were apple blight, blister canker, and apple blotch, and the more important insects were the codling moth and the apple and plum curculios.

Harvesting costs averaged for picking, 6 cts, per bushel; packing, 16 to 25 cts, per barrel; and hauling 2.2 cts, per barrel per mile. Of the orchards visited 76.5 per cent were operated by owners and 23.5 per cent by tenants. The average size of the farm was 102 acres and of the orchard 17 acres. Seventy per cent of the orchard men were of the opinion that the orchard was more profitable than other farm crops.

Experiments with fertilizers on cranberries, J. H. Voornees (*New Jersey Stas. Rpt. 1913, pp. 384–388*).—Outlines are given of some cooperative fertilizer experiments which have been started on a number of cranberry bogs in New Jersey. The work thus far outlined includes the application of single elements derived from different sources as well as a number of complete mixtures,

Strawberry growing, C. T. Ames (Mississippi 8ta, Bul. 165 (1914), pp. 21-23, flg. 1).—Data are given on costs, yields, and returns from a five-acre strawberry field for the years 1908 to 1913, inclusive, together with brief notes on the culture of strawberries in the latitude of the Holly Springs substation.

During the first four years a net average of \$84.85 per acre was secured from the 5-acre field. The net returns for the last two seasons was \$30.63, or an average of \$66.80 per acre for the six years.

Citrus orchard heating, A. M. McOmie (Arizona Sta. Rpt. 1913, p. 250).—A brief statement of results secured in protecting citrus groves from frost injury.

The data collected at the station farm, where one coal pot to every tree was used during the cold periods of December 22 and 23, 1912, and January 5, 6, and 7, 1913, indicate that when temperatures lower than 23° F, are reached little benefit results from their use. At the same time two vigorous yearling Mediterranean Sweet trees were only slightly injured when exposed to a temperature of 11° F, on January 7, 1913, while an adjacent weak tree of the same variety was killed to the ground. This test suggests that it may be possible to develop the citrus industry in Salt River Valley by a careful selection of hardy varieties and the maintenance of high individual tree vigor.

The planting and care of shade trees, F. E. Buck (Canada Expt. Farms Bul. 19, 2. ser. (1914), pp. 24, figs. 7).—This bulletin contains practical directions and advice in the selection of shade trees, their planting, transplanting, and subsequent treatment and care, with notes on the principal injuries and unfavorable conditions to which shade trees are subjected, especially in towns and cities. Lists of varieties suitable for street and home planting in Canada are also given.

FORESTRY.

Forest planting in the eastern United States, C. R. TILLOTSON (U. S. Dept. Agr. Bul. 153 (1915), pp. 38, pls. 7, flg. 1).—A treatise on the establishment of forest plantations in the eastern United States, discussing the propagation of nursery stock, methods of planting, including costs and merits of the different

methods, time of planting, preparation of the soil, spacing, cultivation, thinning, pruning, choice of species for mixed plantations, protection, yields, and returns. Each species recommended for planting is considered with reference to its silvicultural requirements, soil adaptation, planting distances, planting method, products, and age of maturity, with reference to the prairie, central hardwood, and northeast regions. Introductory considerations deal with the opportunities for forest planting and the present status of forest planting in the eastern United States. Data on the prices of nursery stock, officers in charge of forestry in various States, together with literature dealing with planting are appended.

Forest, shade, and ornamental trees, O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpl. Edgeley Substa, 1912, pp. 44-50).—Notes are given on the behavior of a number of trees and shrubs which have been tested at the substation with reference to their value for shelter belts, windbreaks, hedges, and ornamentals.

The Araucaria woods of Chile, R. E. BAQUEDANO (Bol. Bosques, Pesca i Caza, 2 (1914), No. 10, pp. 509-524, figs. 10).—This embraces the results of a survey of the Araucaria forests of Chile with reference to their extent and distribution, habitat, amount of standing timber, natural products, possibilities of exploitation, etc.

The eastern hemlock, E. H. Frothingham (U. S. Dept. Agr. Bul. 152 (1915), pp. 43, pls. 5, figs. 3).—This bulletin discusses the eastern hemlock with reference to its geographical and commercial range; amount and value of standing timber; utilization; structure and development of the tree; associated species; effect of light, soil, and moisture on the composition of the stand; reproduction; rate of growth; susceptibility to injury; and the status of hemlock in forest management. A number of volume tables, applicable chiefly to average trees in the Lake States and Southern Appalachian region, are appended.

The author concludes, in brief, that hemlock grows too slowly and is of too little commercial value to be recommended for planting or for encouragement among natural second growth as a timber tree. The management of hemlock will ultimately be restricted to lands useless not only for agriculture but also for growing many kinds of commercial timber. It is desirable as a decorative tree for parks, and its heavy foliage and shade endurance give it exceptional value for the protection of stream sources. By virtue of its tolerance of shade hemlock adapts itself for growth as a subordinate stand among other kinds of timber. In such cases it materially increases the yield per acre and at the same time protects and enriches the forest soil, thereby tending to accelerate the growth of the other species.

The life history of lodgepole pine in the Rocky Mountains, D. T. Mason (U. S. Dept. Agr. Bul. 154 (1915), pp. 35, pls. 5, fig. 1).—In this bulletin the author discusses the lodgepole pine with reference to its geographical distribution and altitudinal range; size, age, and habit; climatic, soil, moisture, and light requirements; reproduction; growth; causes of injury; associated species; permanency of lodgepole type; ground cover; age classes; and yield.

[Relative success of timber-producing species at the Avondale Forestry Station] (Gard. Chron., 3. scr., 57 (1915), No. 1468, p. 77).—A summary of results secured during the first five years in growing various conifers and broad-leaved species at the station. The trees are arranged in order of their rate of growth and with reference to their hardiness.

Report on supplies of home-grown pit wood in England and Wales, T. H. MIDDLETON (Bd. Agr. and Fisheries [London]. Rpt. Supplies Home-Grown Pit Wood, England and Wales, 1914, pp. 13).—This report embraces the results of

a survey which was made with a view to securing a home supply of mine props and other mining timber to take the place of that imported previous to the present war.

The hardness of woods, G. Janka (Mitt, Forstl. Versuchsw. Österr., No. 39 (1915), pp. VII+117, pls. 4).—In continuation of previous investigations (E. S. R., 20, p. 754) the author conducted hardness tests of some 286 kinds of coniferous and deciduous woods. Determinations were also made of the specific gravity, compressive strength, and shrinkage of the woods. The results are here presented in detail and discussed at length. The investigation was conducted primarily with a view to formulating a numerical classification of the hardness property of different kinds of native and foreign woods occurring in the Vienna trade.

Investigations on the accuracy of volume computations of stems by using the average diameter and length, M. Kunze (Hitt. K. Sächs. Forstl. Versuchsanst. Thurundt, 1 (1912), No. 1, pp. 54).—The author here presents a study of volume and length measurements for various kinds and classes of trees in Germany.

The general conclusion is reached that the form factor of unbarked stems decreases regularly with an increasing average diameter and increases regularly with an increasing stem length. This relation was most marked with pine trees. The influence of diameter and length on the form factor is somewhat less when the bark is removed, but the variation of the form factor due to the absence of bark in the individual species is so small as to be negligible.

DISEASES OF PLANTS.

Report of the botanist and plant pathologist, H. W. Barre (South Carolina Sta. Rpt. 1914, pp. 20-25).—The author reports additional investigations on the anthracnose of cotton, studies of which have been in progress for a number of years. In undertaking to control this disease the hot-water treatment has been investigated, and there was found to be a difference of about 20° C. between the thermal death point of the fungus in culture and the temperature at which the seed is killed. Following up this information it was found that cotton seed would stand a treatment of 75° C. in water for 10 minutes without injury. Plants that have been grown to maturity from treated seed have shown no presence of disease. In cooperation with the North Carolina and some other experiment stations variety tests of cotton for resistance to authracnose are being carried on, but the author states that while there is considerable variation in the amount of disease on different varieties there has thus far been found no indication of very marked resistance.

Notes are given of studies that have been begun on bacterial diseases of cotton and on some physiological disturbances of the cotton plant.

Under the author's direction a plant disease survey of the State is being made, and one of the important discoveries of the past season was the occurrence of *Physoderma zea-maydis* on corn. Some cooperative work is briefly reported on the wilt of cotton and cowpeas, which is carried on with this Department and with planters throughout the State.

Notes of some plant diseases of 1913, W. P. Fraser (Ann. Rpt. Quebec Soc. Protec. Plants [ctc.], 6 (1913-14), pp. 45-50, figs. 3).—The following diseases were noted on the farm of Macdonald College in 1913:

Downy mildew of alfalfa (*Peronospora trifoliorum*) was held in check, probably by the very dry summer of 1913. No effective control measures have been found. Root and stem rot (*Sclerotinia trifoliorum*) was not as prevalent as in 1912 on field alfalfa, but clover grown on experimental plats suffered severely.

Rotation of crops for several years is recommended. This fungus, it is thought, may not be distinct from 8. libertiana, which attacks vegetables, particularly in storage, and was common in 1912.

European apple free canker (Nectria gattigena) was found in an orchard of the college. This is supposedly the first report of this fungus on apples in Quebec, though it is thought to be common in the province.

Pea blight (Ascochyta pisi) was noted, but was not troublesome in 1913, Septoria pisi was common in some plats. These blights are kept under control by seed selection and rotation.

Millet smut (Ustitago panici-miliacci) was very serious on Panicum miliaccum. Formalin treatment of the seed controls the disease.

Stripe disease of barley (Helminthosporium gramineum), while severe on oats and on Mansury barley, did not attack other barleys. Formalin treatment gave good results.

Tip burn of potato was severe, being favored by the dry weather, decreasing the vitality of the plants. Conservation of moisture and control of insects and fungi by spraying held the disease in check. Tomato blossom end rot was prevalent, owing also to dry weather.

Raspberry cane blight (*Coniothyrium fuckelii*) was also prominent during the dry summer weather. No effective measures of control are known, but cutting out and burning diseased canes and cutting old canes as soon as the berries are picked helps to check the spread of the disease.

[Plant diseases in England], R. H. Biffen (Jour. Roy. Agr. Soc. England, 74 (1913), pp. 374-376).—This is a part of the report of the botanist for 1913 and deals very briefly with cases reported or sent in of diseases affecting cultivated plants.

Bacillus amylobacter seemed to attack potato tubers already infected by Phytophthora infestans. One case of black stalk rot, due to B. melanogenes, is noted. It is thought that the disease may be planted with the seed tubers. A case suspected to be Spongospora scabies was thought to be due to gritty soil constituents (as coal ashes), or to the excessive use of kainit. Uromyces between and Peronospora schaehtii are reported on mangolds, also mildew and club root of swedes. Clover sickness is reported as prevalent, and the use of clovers in rotation not oftener than once in six years is recommended. Bunt of wheat, though reported as being spread by traveling thrashing machines, is easily controlled by the copper sulphate or the hot water treatment.

The fruit diseases reported are peach curl, apple canker, leaf scorch, silver leaf, and strawberry spot. *Podosphara leucotricha*, the cause of apple mildew, was found to be in itself parasitized by a species of Cicinnobolus.

Outbreaks of white rust (Cystopus candidus) on white mustard and of celery spot (Scptoria petrosclini apii) were reported too late for effective control.

Other diseases, as larch canker, mildew on peas, asters, etc., and a spot disease on tobacco were dealt with,

The downy mildews, E. M. Du Porte (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 6 (1913-14), pp. 33-38, figs. 3).—This is a brief discussion of some Peronosporaces affecting economic plants, with a key to the genera.

The chemical composition of Bordeaux mixture and its soluble copper content, V. Vermorel and E. Dantony (Compt. Rend. Acad. Sci. [Paris], 159 (1914). No. 3, pp. 266-268).—Reporting a study of the conditions leading to the formation of different compounds in Bordeaux mixture and of the question as to whether the alkaline mixture is free from soluble copper, the author states that when concentrated milk of lime is poured very rapidly into a dilute solution of copper sulphate the visible result is the blue color of stable copper

hydrates, but that when the lime water is poured very slowly the green color of basic copper sulphate is seen. The alkaline mixture in process of application is said to contain abundance of dissolved copper for fungicidal purposes,

Further observations on the fungicidal action of Bordeaux mixture, B. T. P. BARKER and C. T. GIMINGHAM (Abs. in Rpt. Brit. Assoc. Adv. Sci., 1913, p. 767).—This gives briefly the substance of a contribution already noted from another source (E. S. R., 32, p. 243).

The physiological effect of the absorbed copper on the treated plant is also under investigation.

Seed treatment to prevent diseases in field crops, O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpt. Edgeley Substa., 1905, pp. 19, 20).—Directions are given for the treatment of cereals, flax, and potatoes with formaldehyde solution for the prevention of the various diseases.

Foot disease of cereals, Schribaux (Bul. Soc. Nat. Agr. France, 74 (1914), No. 4, pp. 443-423).—Tests were made in 1913 with a number of wheat varieties, also some hybrids thereof, both in test plats and in the open field, as regards susceptibility to foot or stalk disease. One of these varieties, Poulard d'Australie, seemed almost entirely resistant, this variety being later than native wheats and showing a less rank vegetative growth in early spring. In general, plats from seed of a given variety sown experimentally in both fall and spring showed fewer affected plants from the spring sowing. It is claimed that moderate vegetative growth and free access of sunlight are unfavorable to development of foot disease of cereals.

A cabbage disease, W. B. Grove (Jour. Roy. Hort. Soc., 40 (1914), No. 1, pp. 76, 77, fig. 1).—The author gives a brief description and the life history of a cabbage disease prevalent in the Isle of Wight, Cornwall, and elsewhere during the past winter.

The perfect stage, known as *Mycospharella brassicicola*, is said to be somewhat rarely found in that section, but the pycnidial stage occurs more commonly and abundantly and does considerable damage. This stage is said to have been described formerly as *Asteroma brassica*, but the author claims it should be classed as a Phyllosticta and he describes this form under the name *P. brassicicola* n. comb.

The only view given regarding remedial treatment is that such measures would probably prove to be of more expense than benefit in this case.

A note on celery leaf spot disease, F. J. Chittenden (Ann. Appl. Biol., 1 (1914), Vo. 2, pp. 204-206).—The author states that he has been able to demonstrate the infection of seedlings from seeds diseased by adhering spores of Septoria petrosclini apii which may be found, it is said, on about 90 per cent of the celery seed offered for sale. The fungus also attacks celeriac. The disease appears to spread more slowly during the seedling stage than later in the season.

Bordeaux mixture is said to afford satisfactory protection.

Diseases of peas (Jour, Bd. Agr. [London], 21 (1914), No. 5, pp. 418-423, pl. 1).—Powdery mildew of peas (Erysiphe polygoni), said to attack also many weeds, is controlled by early spraying with liver of sulphur, 1 oz. to 4 gal. of water. Mildew (Peronospora viciae), attacking many cultivated and wild legumes, requires employment of rotation, with Bordeaux mixture where outbreaks occur. Rust (Uromyces fabae), which also attacks many members of this family, is most satisfactorily controlled by the destruction of the teleutospores, preferably by burning the vines. Black root rot (Thielavia basicola), said to be almost omnivorous and described as attacking young pea seedlings, lives saprophytically in humus soils. Formalin of about 1 per cent strength

applied at the rate of 1 gal, per square foot, is said to destroy the fungus if the soil is covered with coarse sacking for a few days, after which the fumes must be permitted to escape before planting the seels. Pea spot (Ascochyta pisi) attacks also wild legumes. It is stated that this fungus may be controlled with Bordeaux mixture if applied on its first appearance.

Leaf spot and some fruit rots of peanut, F. A. Wolf (Alabama Col. Sta. Bul. 180 (1914), pp. 127-150, pls. 5).—The author describes three fungus diseases of peanuts occurring in Alabama. These are leaf spot, due to Cercospora personala, a red rot of the peanuts caused by Neocosmospora vasinfecta, and a sciential rot due to Scientium rolfsii.

The most prominent symptom of the leaf spot disease is said to be the presence of chestnut brown areas on the leaves, petioles, and stems, which may result in considerable defoliation, impairing the hay crop and indirectly reducing the yield of peannts. Crop rotation and seed disinfection are recommended as preventive measures, spraying being considered impracticable. On account of the fact that the fungus has been found to hibernate on diseased leaves lying in the field, attention is called to the necessity of their destruction.

The fungus causing the red rot is not considered parasitic, and it occurs on peanuts only as a saprophyte. Digging the crop when mature without delay, it is thought, would reduce the amount of injury sometimes done.

The sclerotial rot is due to a parasite, both the shell and the kernel being destroyed. In addition to peanuts the fungus causing this disease is known to occur on a large number of host plants and as a consequence no remedial measures such as rotation can be recommended for its control.

A bibliography is appended.

Potato diseases, A. S. Horne (Ann. Appl. Biol., 1 (1914), No. 2, pp. 183-203, figs. 8).—This is a brief examination and discussion of several contributions from various authors regarding diseases of potato, including Chrysophlyctis endobiotica, Phytophthora infestans, sprain, Fusarium solani, curl, Spongospora solani, and other diseases.

Potato scab, B. F. Lutman and G. C. Cunningham (Vermont Sta. Bul. 184 (1914), pp. 64, pls. 12, figs. 7).—In a previous publication attention was called to the pathology of the potato scab (E. S. R., 20, p. 539). In the present bulletin a detailed account is given of the investigations, from which it is concluded that the stimulation of cork products is due to the growth of an organism, resulting in the formation of chemical substances which are absorbed and which cause the cork cells to increase in size and number. According to the authors the organism which has hitherto been referred to as Oospora scabies should be designated as Actinomyces chromogenus.

This organism is widely spread, occurring in practically all soils, but is most numerous in those which are rich in humus. The parasitism of the organism is facultative and may be induced by an alkaline condition of the soil, the presence of moisture, and an abundance of organic matter of the soil. It is believed that some strains of the organism may have developed this character to a greater extent than others, but the authors were unable to recognize any morphological or cultural characters which would distinguish them. The organism is considered to be spread more probably through manure and humus than through scabby potatoes, though the latter should be avoided or thoroughly disinfected.

A weak acidity of the soil instead of a neutral or slightly alkaline condition is considered the most hopeful attack in combating this organism. The use of flowers of sulphur is said to be helpful in diminishing the amount of scab, but may prove harmful to other crops if applied in too large quantities. No

varieties of potatoes have been found that are wholly resistant to this disease, although some differences have been observed. The cause of variation is not known.

A bibliography is included.

Report of the plant pathologist, M. T. Cook (New Jersey Stas. Rpt. 1913, pp. 793-817, pls. 7).—The author reports the discovery of the silver scurf (Spondylocladium atrovircus) of potatoes in the State. Notes are also given of other investigations, and the most common diseases observed during the year are reported according to host plants.

The report concludes with an account of potato field tests carried on under the supervision of G. W. Martin to determine whether finely pulverized sulphur and powdered arsenate of lead can be depended upon to protect the potato foliage from insect injury and fungus disease. Four powdered preparations were used and comparisons made with Bordeaux mixture, Paris green, Pyrox, and two other commercial preparations. It is concluded from the tests made that a mixture of pulverized sulphur and arsenate of lead is practicable and efficient in controlling the Colorado beetle. The most striking results obtained showed the economy of Bordeaux mixture and also the short time required to apply powders. Under the conditions of the experiment the cheapest and most efficient preparation used was a dust mixture composed of three parts of sulphur and one part of arsenate of lead.

Storage rots of potatoes and other vegetables, W. P. FRASER (Ann. Rpl. Quebec Soc. Protec. Plants [etc.], 6 (1913-14), pp. 50, 51).—Brief descriptions are given of black and blue mold rots, late blight rot, dry rot, and soft rot of potatoes. Control measures include crop rotation, careful harvesting in dry weather, and storage in clean, moderately dry cellars at not above 40° F.

The biology of the apple canker fungus, S. P. Wiltshire (Abs. in Rpt. Brit. Assoc. Adv. Sci., 1913, p. 714).—Nectria ditissima is said to be a genuine wound parasite, succeeding only in case of injury deep enough for the fungus to reach the wood before it is shut off by the formation of a layer of phellogen. The fungus traverses the intercellular spaces of the cortex, breaks through the cell walls of phloem and cambium, and traverses the woody elements via the pits in the walls, the medullary rays offering no special means of access to the interior.

The host reacts by the formation of phellogen, of abnormal wood cells resembling those of the medullary rays, and of wound gum in the wood vessels. The mycelium normally does not spread greatly. Inoculation usually occurs by means of injuries due to frost or aphids. Relatively immune varieties of apple may be infected through injuries under suitable conditions, the determining factors being mostly physiological.

Observations on the life history of the American gooseberry mildew, E. S. Salmon (Ann. Appl. Biol., 1 (1914), No. 2, pp. 177–182).—The author, referring to his previous article (E. S. R., 31, p. 545), gives results of a further examination of material, concluding that some of the perithecia of the American gooseberry mildew (Sphærotheca mors-uræ) which are produced in England either do not reach maturity or do not survive the winter. It is claimed that no case of primary infection by ascospores from overwintered material still present on the shoot has been established. It is thought that ascospores from mature perithecia lodged in bark crevices, bud scales, etc., may possibly be the ones which become the source of the early infection noted.

The control of American gooseberry mildew, G. C. Gough (Gard. Chron., 3. ser., 56 (1914), Nos. 1454, pp. 303, 304; 1455, p. 319).—Giving the advantages and disadvantages of various methods of dealing with American gooseberry mil-

dew as shown by experience in many typical cases and in representative parts of England for some years past, the author states that the order of the Board of Agriculture and Fisheries requiring the destruction of all diseased bushes has been withdrawn, although destruction is still recommended where bushes are old and badly diseased. Owing to the habits of the fungus as described, spraying has proved impracticable in a large number of cases, and it is thought to be of value only in cases where the disease has appeared recently and is noted in time (soil infection being slight or absent), or where the object is to keep the fruit free from disease for marketing. No definite or uniform success has attended soil treatment. The value of pruning if done early and properly Is said to be decided, but to have its own disadvantages, which are outlined, chief among these being its usually late or imperfect accomplishment.

Banana disease on the Clarence River (Agr. Gaz. N. S. Wales, 25 (1914), No. 9, pp. 809, 810).—For the past two or three years a new disease has been noted among bananas on the Clarence River. It is known locally as pear top, bunch top, blight, or rust. Investigation has not shown it to be caused by bacteria or fungi and it is thought to be of physiological origin. Soil exhaustion is suggested by the facts that it appears only on old plantations and that sugar cane on such soils shows a similar habit.

Remedies suggested are thinning, rotation, and fertilizing according to formulas given.

Cacao canker and its control in Java, C. J. J. VAN HALL (Meded, Proefstat, Midden-Java, No. 6 (1912), pp. 17).—The author, referring to the claim of Rorer (E. S. R., 27, p. 750), confirmed by Rutgers (E. S. R., 29, p. 248), that Phytophthora faberi is the cause of both cacao canker and black or brown pod rot of cacao, notes the facts that in artificial cultures P. faberi is quickly overgrown by Fusarium colorums associated therewith, and may disappear from the margins, easily giving the impression that F. colorans is the primary cause of the trouble, which is really due to P. faberi.

Control measures recommended include the removal of all cankered fruits or of spots on the tree, the production of unfavorable life conditions for the parasite (as by better control of shading, involving attention to both the cacao trees and others growing therewith), and the prevention of infection or or spread in case of incipient attack, as by the use of such fungicides as Bordeaux mixture.

Notice relating to citrus canker, E. S. Tucker (Louisiana Stas, Crop Pest Notice 1 (1914), pp. 2).—Attention is called to the occurrence of the citrus canker in Louisiana and a plea is made for the prompt cooperation of citrus growers to secure its eradication.

Coffee leaf disease, W. SMALL (*Uganda Dept. Agr. Circ. 1* (1914), pp. 8).— This disease (due to *Hemileia vastatrix*) is said to to be endemic in Uganda, having been present on practically every tree of native coffee for many years, but to have been only recently recognized definitely as to species and importance. It is said to be known now in all coffee-growing countries of the Old World. In 1913 losses on areas of recent planting amounted to 30 per cent in many instances, but on some of these areas the trees afterwards showed new shoots and foliage and some promise of good crops.

Such preventive measures are recommended as give access of sunlight and wind. These include planting in dry localities with wide spacing, the plats so arranged that the prevailing winds may sweep them crosswise rather than lengthwise. Destruction of all fallen and visibly diseased leaves is considered important. Careful selection of material for planting, appropriate manuring, supervision of native trees, etc., are measures relied upon to reduce the amount

of the disease, which is expected to appear sooner or later on every estate of cultivated coffee in Uganda.

Diseases and pests of Hevea in the Federated Malay States, A. A. L. RUTGERS (Dept. Landb., Nijr. en Handel [Dutch East Indies], Meded. Afdeel. Plantenziekten, No. 4 (1913), pp. 8-16).—This is mainly a discussion of Hevea as affected by canker in relation to weather, particularly rainfall; spacing In planting, also interplanting with other growths; pruning; and employment of water in connection with tapping operations.

Fomes semitostus, the cause of a root mold, is also briefly discussed.

Observations upon a disease of carnations, M. A. BLAKE (New Jersey Stas. Rpt. 1913, pp. 168-170. fig. 1).—The author reports having noted at different times a disease of carnations in which there was a red spotting of the leaves of red varieties and of some dark pink varieties. The light pink, white, or yellow varieties may be affected by the spots, but less commonly and the spots are more translucent. The injured leaves on all varieties gradually turn brown, giving the plants a sickly and dying appearance.

Various theories have been advanced as to the cause of this trouble. The author states that experiments have shown that considerable injury often follows the setting of carnation plants in soil that does not dry freely. Excess of moisture does not appear to be one of the important factors in the matter, but it seems to be a soil condition. It is thought that if proper cultural conditions are maintained the amount of injury may be reduced. Cuttings from diseased plants have been propagated without showing any sign of the disease.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

Animal communities in temperate America as illustrated in the Chicago region.—A study in animal ecology, V. E. Shelford (Geogr. Soc. Chicago Bul. 5 (1913), pp. XIII+362, pl. 1, figs. 315).—The author defines ecology at present as "that branch of general physiology which deals with the organism as a whole, with its general life process, as distinguished from the more special physiology of organs, and which also considers the organism with particular reference to its usual environment."

The several chapters of this work deal with the subject under the headings of man and animals; the animal organism and its environmental relations; the animal environment, its general nature and its character in the area of study; conditions of existence of aquatic animals; animal communities of large lakes (Lake Michigan), streams, small lakes, and ponds; conditions of existence of land animals; animal communities of the tension lines between land and water, of swamp and flood plain forests, of dry and mesophytic forests, and of thickets and forest margins; and prairie animal communities.

A bibliography of 214 titles and author and subject indexes are included.

Preliminary report on the mammals of North Dakota, V. Balley, W. B. Bell, and M. A. Brannon (North Dakota Sta. Circ. 3 (1914), pp. 20).—Following a brief discussion of life and crop zones, habits of animals, and preparation and care of specimens, the authors present brief accounts of some 80 species of mammals known to occur in North Dakota.

Studies in the comparative size of the red blood corpuscles of birds, CIII TSAU WANG (Jour. Ent. and Zool., 6 (1914), No. 4, p. 221).—Studies of the erythrocytes of 17 species are reported upon.

Entomology, A. W. Morrill (Arizona Sta. Rpt. 1913, pp. 270, 271).—Particular attention is said to have been given the harvester ant (Pogonomyrmex barbata) and the alfalfa seed chalcis fly (Bruchophagus funcbris). Through

the use of sheet-iron covers inclosing circular areas 4 and 10 ft. in diameter, respectively, it was found that a maximum dose of 2 oz, of carbon bisulphid, costing approximately 1 ct., completely eradicated the ant colony when the ground was still quite wet following irrigation. With soil insufficiently moist the results were not dependable even with much larger doses. The author considers it practicable for an individual possessing an outfit of ten or more such covers to take contract work on a large scale.

In Arizona, the alfalfa seed chalcis fly, also known as the clover seed chalcis tly, is one of the most destructive pests, not only on account of direct injury, but through its keeping many alfalfa growers, who would otherwise be interested, from attempting to make a seed crop. A trap crop experiment was carried on during the year, in which a border of some 40 ft. all around a 10-acre field was left uncut at the time of the second regular hay cutting on May 5, when the remainder of the field was cut and the hay stacked. This border was allowed to bloom and set seed which attracted the seed flies in the vicinity, it being the only alfalfa having seed available for the oviposition of the eggs. This border crop was cut and the hay removed from the field before the insects had sufficient time to reach maturity. While it is believed that the bordering trap crop actually afforded considerable protection, the practical results appeared to be mostly negative since the crop from the field averaged 210 lbs, per acre, which was not more than would be expected under ordinary conditions. It is pointed out, however, that the experiment was conducted under unfavorable conditions since a nearby grain field infested with bur clover produced myriads of the seed flies of the first brood which spread over the surrounding fields.

Report of the entomologist, T. J. Headlee (New Jersey Stas. Rpt. 1913, pp. 633-789, pls. 4, figs. 3).—The insects of the year briefly noted, information relating to which is largely based on correspondence, include various species of plant lice, scale insects, the false apple red bug (Lygidea mendax), rhododendron lace bug (Leptobyrsa explanata), flea-beetle (Epitrix cucumeris), which proved to be the worst insect enemy of the potato during the year, fruit bark beetle (Scolytus rugulosus), which attracted attention by its work on peach, hickory bark beetle (S. quadrispinosus), etc. Insects mentioned as of special interest, either because new to New Jersey records or because of the danger of their introduction, include an undetermined buprestid borer on Rosa rugosa nursery stock, a pine scolytid (Myclophilus piniperda), which bores out the tips of the central shoots of Scotch firs, a sawtly (Kaliosysphinga dohrnii) new to New Jersey found doing considerable damage to alders in the nursery, etc.

In order to determine the relative value of a dusting mixture as compared with the normal liquid treatment, a series of orchard and potato tests were made. The dust was composed of 20 per cent powdered "Electro" arsenate of lead and 80 per cent very finely divided sulphur. Eleven and one-fourth lbs. of paste, consisting of the same finely divided sulphur with about 50 per cent water, and 13 lbs, of the powdered lead arsenate were used to each 50 gal. of water. Application of the dust treatment to peaches at Glassboro is given credit for exerting a better control of the plum curculio than the paste or self-boiled lime-sulphur, and consequently for holding a much larger percentage of the total set on the entire tree. The results of similar peach tests at Vineland indicated "(1) that either dust or paste applied with sufficient frequency will give reasonable control of plum curculio and seab fungus, (2) that when dust or paste are applied no more frequently than self-boiled lime-sulphur arsenate of lead they are not so effective as the standard wash (3) that the paste sulphur and lead, which are much easier to make up and apply, are almost as efficient in insect and scab fungus control as the self-boiled mixture, (4) that

the dust must have more frequent applications than either the self-boiled or paste to produce anything like equal results."

No definite results were obtained from the tests with apples and potatoes. The experiments with corn show: "(1) That when the poisonous dust is properly placed on the corn silks and maintained throughout the period the silks are green and succulent, more than 75 per cent of the normal damage is prevented, (2) that any machine which distributes the dust in such a fashion as to produce only a light coating on exposed parts is of little or no value in corn earworm control, (3) that the dust must be maintained throughout the period during which the silks are green and succulent, (4) that the 50 per cent mixture is the most efficient, because its physical condition is better (drier) than the 75 per cent, and has more strength than the weaker mixture."

Work with the peach borer carried on in continuation of that of the previous year (E. S. R., 30, p. 355), in which each of 28 5-year-old peach trees was coated with tree tanglefoot from the point where the large roots came off to a point 6 in above the surface of the soil, showed that although in common with other substances the tanglefoot reduces the infestation, it not only fails to prevent it completely, and if used regularly is likely to destroy the trees.

In summing up the results of fly work the author states that "the fly control campaigns in the city of New Brunswick, on the college general farm, and on the college dairy farm, have shown: (1) The need of cooperation betwen the fly-suppressing agency and the persons running the premises on which a fly campaign is in progress; (2) the utter insufficiency of the Hodge and other fly traps as a complete control—demonstration of the fact that they are at best but an adjunct; (3) the impracticability of obtaining anything like a general adoption of the Hodge garbage can trap and its ineffectiveness as a destroyer of the house fly, the really serious carrier of infection; (4) the surpassing importance of eliminating the fly-breeding places; (5) the usefulness of iron sulphate and carbon bisulphid as larvicides; (6) the effectiveness of sulphur as a destroyer of adult flies; (7) the effectiveness of even incomplete work on fly control."

A report upon the mosquito work for 1913 follows (pp. 719-789). The author states in general that the work has proved as successful as the seasonal conditions would permit. A brief account of the occurrence of the mosquitoes of the year is included.

Summary of entomological information during 1914 (Agr. News [Barbados], 13 (1914). No. 330, pp. 408, 409).—A brief review.

Proceedings of the Entomological Society of British Columbia (*Proc. Ent. Soc. Brit. Columbia, n. scr., No. 4* (1914), pp. 83).—Among the more important papers here presented are the following: Insect pests of the year in the Victoria District, by E. H. Blackmore (pp. 11–14) and in the Okanagan District, by W. H. Brittain (pp. 14–19); those economically important in the lower Fraser Valley. Vancouver District, by R. C. Treherne (pp. 19–33); Bee Diseases in British Columbia, by F. D. Todd (pp. 33–36); The Tent Caterpillar (*Malacosoma crosa*), by T. Wilson (pp. 36–38); Preliminary Note on the Work of *Eriophycs* sp. upon Apples, Apricots, and Plums (pp. 38, 39), and Ants as Fruit Tree Pests (p. 39), by W. H. Brittain; Notes on the Life Histories of Bloodsucking Diptera of British Columbia, with Special Reference to the Tabanidæ, by S. Hadwen (pp. 46–49); A Review of Applied Entomology in British Columbia, by R. C. Treherne (pp. 67–71); and Mites, Their Classification and Habits, with Some Observations on Their Occurrence in the Okanagan, by J. S. Dash (pp. 71–78).

A preliminary survey of forest insect conditions in British Columbia, J. M. SWAINE (Canada Expt. Farms Bul. 17 (1914), 2. ser., pp. 41, pls. 2, figs. 22).—

This is a report of a survey made during the summer of 1913 with the view of determining the location and extent of the chief forest insect injuries, and to decide upon proper control measures for the more serious outbreaks. But a small portion of the southern part of the forest area of British Columbia could be covered.

The bull pine, or western yellow pine (*Pinus ponderosa*), occurs in British Columbia only in the southern part of the interior. It is subject to attack throughout its range in British Columbia by three destructive species of bark beetles, viz. the western pine bark beetle (*Dendroctonus brevicomis*), the western white pine, or mountain pine bark beetle (*D. monticolæ*), and the red turpentine bark beetle (*D. valens*), and by a number of pests of lesser importance. The most important and extensive injury was found to occur about Princeton, in the southwest portion of the bull-pine area.

The mountain pine, or western white pine (*P. monticola*), occurs in British Columbia from the valley of the Columbia River to Vancouver Island. It is subject to attack from several species of bark beetles, *D. monticola* being particularly destructive in the interior and on Vancouver Island.

The lodgepole or black pine (*P. murrayana*) occurs throughout the interior of British Columbia and is subject to attack by *D. monticolæ* and *D. murrayanaw*, and by a number of species of secondary importance.

The Douglas fir (Pscudotsuga mucronata) extends over a very wide area in the southern half of British Columbia, from the eastern foot-hills of the Rockies to the coast and Vancouver Islands, with a very irregular northern and northwestern limit; in the area covered by the survey there was no very extensive insect injuries found. The Douglas fir bark beetle (D. pscudotsugæ) is thought to be the most serious enemy and a number of other species are important secondary enemies.

The Sitka spruce occurs in British Columbia throughout the coast region and on Vancouver Island. Its most injurious insect enemies are the Sitka spruce bark beetle (*D. obcsus*) and the western spruce gall louse.

Brief accounts are given of the ambrosia beetles, also known as timber beetles or pin-hole borers, of which the two most important on conifers are *Gnathotrichus retusus* and *G. sulcatus*, and of the Pacific Coast timber beetle, *Platypus* sp., which is abundant on the coast and island. Brief mention is made of the larger wood borers of the families Cerambycidæ and Buprestidæ.

Accounts of the life history, habits, and injury of, and control measures for the most important species discussed in the buildin are included. A map, showing the limits of forest trees in southern British Columbia, is added.

Concerning infection through insects, T. A. VENEMA (Hyg. Rundschau, 24 (1914), No. 20, pp. 1073-1083).—A summarized account of the transmission of disease organisms by insects.

Transmission of disease by native bloodsucking insects, A. Schuberg and W. Böing (Arb. K. Gsndhtsamt., 47 (1914), No. 3, pp. 491-512, fig. 1; abs. in Rev. Appl. Ent., 2 (1914), Ser. B. No. 11, p. 169).—This third paper (E. S. R., 28, p. 756) deals with the experimental transmission of anthrax and of streptococci to the sheep and goat by the stable fly (Stomoxys calcitrans), a brief account of which has been previously noted from another source (E. S. R., 29, p. 760).

A contribution to the biology of sewage disposal, J. W. H. Johnson (Jour. Econ. Biol., 9 (1914), Nos. 3, pp. 105-124; 4, pp. 127-164, figs. 33).—In the course of this discourse the author deals at some length with the sewage fly or moth fly (pp. 136-143), particularly Psychoda phalanoides and P. sexpunctata; and the water spring tail (Achorutes viatious) (pp. 143-149). Where circumstances

favor their development the psychodids may appear in myriads at certain times of the year and be carried by the wind into inhabited neighborhoods so as to give rise to an intolerable nuisance.

The biology of the three pests named is dealt with.

The grasshopper problem and alfalfa culture, F. M. Webster (U. S. Dept. Agr., Farmers' Bul. 637 (1915), pp. 10, figs. 8).—Three species of grasshoppers are said to be largely responsible for the injury to alfalfa in the United States, namely, the differential grasshopper (Metanoplus differentialis), the two-striped grasshopper (M. bivillalus), and M. atlanis, a more or less migratory species. Hardly a season passes without more or less serious outbreaks of these pests. The publication consists largely of a popular account of them, their natural enemies, and preventive and remedial measures.

Thrips attacking the leek (Thrips tabaci), A. VUILLET (Rev. Phytopath, Appl., I (1913), No. 10, pp. 136, 137; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 5, pp. 278, 279).—In 1913 an attack by T. tabaci in the Department of Sarthe resulted in a reduction of the leek crop by 50 per cent.

Contribution to the knowledge of the sucking phenomena of plant lice and the reaction of plant cells, F. Zweigelt (Cenlbt, Bakt, [clc.], 2, Abt., 42 (1914), No. 10-14, pp. 265-335, pls. 2, figs. 7).—An anatomo-cytological study of plants and coccids and aphidids. A bibliography of 65 titles is appended.

Phylloxera galls affecting pecan trees, E. S. Tucker (Louisiana Stas, Crop Pest Notice 2 (1914), pp. 8, fig. 1).—This is a brief account of the occurrence and nature of galls on pecan trees in Louisiana caused by Phylloxera caryacaulis, P. devastatrix, and P. perniciosa.

The oak scale and its control (Lecanium quercifex), W. F. TURNER (Alabama Col. Sta. Circ. 28 (1914), pp. 105-110, fig. 1).—The oak scale is the source of considerable injury in Alabama and the other Gulf States to oaks, several species of which, particularly the water oak (Quercus nigra), are the principal street and shade trees. The injury, while not confined to the young trees, is much less apparent on the older ones. The pest is becoming more and more abundant every year and constitutes a very serious problem in the care and maintenance of shade trees.

At Auburn, Ala., egg deposition commences early in April and continues for about three weeks. Counts made of the eggs deposited by three females gave 2,245, 5,000, and 5,262, respectively. The incubation period was found to be about 26 days. The young are very active and may travel considerable distances before settling, which occurs principally along the main or larger lateral veins of the leaf. They may remain active for a considerable length of time even after they reach the leaves. After settling they remain on the leaves until fall, apparently remaining in the first stage throughout the summer. Migration to the small twigs, where they remain dormant throughout the winter, takes place the last of September. In February when the sap begins to flow growth commences which continues until the last of March when it becomes very rapid and they soon attain their full adult size.

The natural enemies of this species include two undetermined hymenopterous parasites and several lady beetles of which *Chilocorus bivulnerus* is the most important. Spraying experiments have shown Schnarr's insecticide 1:20 and emulsions of Junior Red Engine and Diamond paraflin oils when applied in March to kill about all of the scales with which they come in contact. The emulsions are made by using 2 gal. of either oil to 1 gal. of whale oil soap and 50 gal. of water.

The control of the moth borer, J. J. Quelch (Abs. in West India Com. Circ., 29 (1914), No. 421, pp. 536, 537).—In this paper the author reports studies on the control of the small moth borers (Diatrwa saccharalis and D. cancila),

which cause much damage to sugar cane in British Guiaua. Egg parasites of these pests are said to be particularly effective, at times as high as 95 per cent of the eggs in the field being parasitized.

A wood-boring moth (Agr. News [Barbados], 13 (1914), No. 325, p. 328).—This is a discussion of Duomitus punctifer, an account of which is included in the paper by Bovell and Nowell previously noted (E. S. R., 31, p. 547). The larva of this moth is injurious to a wide range of trees and shrubs and is generally distributed in the Lesser Antilles. It tunnels in the whitewood tree (Tecoma leucoxylon) in all directions in the larger branches and through the middle of the smaller ones even to fine twigs. Its life history is said to resemble closely that of the leopard moth (Zeuzera pyrina).

Relation between the larvæ of vine moths (Cochylis ambiguella and Polychrosis botrana) and the weeds of vineyards and other plants, G. LÜSTNER (Ztschr. Weinbau u. Weinbehandl., 1 (1914), No. 1, pp. 3-35; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 6, p. 826).—In experiments carried out in the fall Cochylis larvæ were observed to be distinctly polyphagous, even devouring emphorbiaceous plants. Experiments with Polychrosis larvæ conducted in the spring showed them to be equally polyphagous.

Contribution to the study of the biology of Hyponomeuta malinella in Roumania, G. Fintzescou (Rev. Sci. Bourbon., 27 (1914), No. 3. pp. 78-80; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 9. p. 564).—The author, who has studied this lepidopteran for many years, reports that there are three generations each year in Roumania.

The bacterial diseases of caterpillars, R. W. Glaser (*Psyche*, 21 (1914), No. 6, pp. 184–190).—This is a brief review of the literature relating to the subject.

The author states that while there seems to be a considerable amount of collateral evidence that caterpillars are subject to bacterial diseases, he is not familiar with a single case where this has been conclusively proved. It is pointed out that many of the authors reviewed agree that the flacherie-like diseases are primarily intestinal affections and that the bacteria concerned are found outside of the intestine, in the body cavity, only during the later stages when the alimentary canal ruptures.

"While it therefore seems possible that some of the caterpillar diseases now grouped under the name of flacheric are intestinal disturbances caused by toxic products liberated within the alimentary tract by specific bacteria, it is not at all unlikely that other diseases affect other parts of the body, such as the disease described by Picard and Blanc [E. S. R., 29, p. 855]. The entire subject, however, is still one for controversy."

A bibliography of 14 titles is appended.

[Cecidomyiid flies attacking willows] (Bul. Soc. Nat. Acclim. France, 61 (1914), No. 1, pp. 24, 25).—The habits of two cecidomyiids, Rhabdophaga rosaria and R. pulvini, which are at times a source of serious injury in oseries are briefly considered. Salix purpurea, S. depressa, S. aurita, and S. cinerca are the species that suffer most from their attack.

Economic and biologic notes on the giant midge (Chironomus (Tendipes) plumosus), A. C. Burrill (Bul. Wis. Nat. Hist. Soc., n. ser., 10 (1913), No. 3-4, pp. 124-163).—This paper deals at some length with the life history and habits of this midge, its natural enemies, economic importance, and remedial measures. An annotated hibliography of 14 pages is appended.

Mosquitoes and sewage disposal, F. Knab and A. Busck (Amer. Jour. Trop. Discases and Prev. Med., 2 (1914), No. 5, pp. 333-338).—The authors point out that certain species of mosquitoes, particularly Culex pipiens and

C. quinquefasciatus, multiply most rapidly in the presence of highly polluted water, and discuss an outbreak investigated that had its origin at sewage-disposal plants.

Stomoxys calcitrans, A. Rutherford (*Trop. Agr.* [Ceylon], 42 (1914), No. 3, pp. 222-225).—This comprises notes on the stable fly (8. calcitrans) with quotations from the literature. The horn fly (*Hamatobia serrata*) also occurs in Ceylon.

On a larva of a species of Muscinæ, living in the nest of Passer griseus in the Kongo, J. Rodham (Rev. Zool. Afric. [Brussels], 3 (1914), pp. 213-217, fig. 1; abs. in Rev. Appl. Ent., 2 (1914), Ser. B. No. 4, p. 69).—Larvae and pupe of a fly belonging to the subfamily Muscinæ were taken from the nests of the gray-headed sparrow (P. griscus) and upon examination the larvae were found to contain avian blood.

Inheritance of the length of life in Drosophila ampelophila, R. R. Hyde (*Proc. Ind. Acad. Sci., 1913, pp. 113-124, figs. 5*).—The conclusions drawn from the author's investigations with the pomace fly are in part as follows:

"Hybrids between the truncate stock and the inbred stock are more vigorous than either parent, as shown by the fact that the hybrid lives 47 days while . . . the flies from the truncate stock . . . live 21.4 days, the females live 18.4 while the males live 26.4 days. The flies from the inbred stock live 37.4 days. The females live 34.5 days while the males live 40.5 days. The shortened length of life of the truncate stock reappears among the grandchildren after skipping a generation when crossed to the inbred stock. . . . Those descended from the truncate grandmother lived 29.5 days. The males lived 32.8 days and the females lived 25.9 days. The flies descended from the truncate grandfather lived 29.3 days. The males lived 31.1 days, while the females lived 27.3 days. It seems not improbable that the length of life and the coming to maturity of the germ cells may be in some way physiologically connected."

Cane grub and muscardine fungus at Cairns, H. Tryon (Queensland Agr. Jour., n. ser., 2 (1914). No. 6, pp. 402-405).—The author states that Metarrhizium anisopliæ is indigenous to Queensland.

[Report of] division of entomology, H. T. EASTERBY (Ann. Rpl. Bur. Sugar Expt. Stas. [Queensland], 1914, pp. 55-57).—A brief statement is presented by A. A. Girault of the results of work with the so-called grub pest or cane beetle (Lepidiota albohirtum), details relating to which will be published later as a bulletin.

Wireworms attacking cereal and forage crops, J. A. Hyslor (U. S. Dept. Agr. Bul. 156 (1915), pp. 34. figs. 8).—In an introduction the author gives a brief account of the feeding habits of the true wireworms (Elateridæ), and also of the false wireworms (Tenebrionidæ). Several hundred species of Elateridæ, which vary enormously in their habits, occur in North America; the majority attack the roots of plants but some live in dead and rotten wood (Alaus, Elater, Adelocera, etc.) and still others (Alaus, Hemirhipus, Adelocera, etc.) are predaceous. Some species abound in heavy moist soil filled with humus (Melanotus, Agriotes, etc.), some prefer well-drained soils (Corymbites), and still others (Horistonotus) are most destructive on high sandy land which is very poor in humus. It is stated that the large luminous elaterid of the West Indies (Pyrophorus luminosus) is a decidedly beneficial insect, since it feeds on the Lachnosterna larvæ in the sugar cane fields.

Brief accounts are given of the life history, habits, injury, occurrence, and remedial measures for some of the more important species, including the wheat wireworm (Agriotes maneus), the corn and cotton wireworm (Horistonotus uhlerii), the inflated wireworm (Corymbites inflatus), the dry-land wireworm

(C. noxius), corn wireworms (Mclanotus communis, M. fissilis, and M. cribulosus), and a large number of species of minor importance. In an account of natural enemies, which follows, it is stated that birds are probably the most important factor in keeping wireworms in check. A list of the birds known by examination of the crops and stomachs to feed on Elateride, as compiled by the Biological Survey of this Department, is given. Other enemies mentioned are a small lizard (Phrymosoma douglasii douglasii) found in the desert regions of the Northwest, and locally known as the sand toad; several species of mites; a dipteran (Therera egressa), the larva of which attacks and feeds upon wireworms; and the fungi Penicillium anisoplia and Mctarrhizium anisoplia.

Remedial measures are discussed under the headings of treatment of seed, soil treatment, and cultural methods. It is stated that thus far cultural methods alone have proved to be of much practical value.

The wavy striped flea-beetle (Phyllotreta sinuata), E. M. DUPORTE (Canad. Ent., 46 (1914), No. 12, pp. 433-435, figs. 3).—The author records observations of this pest in Quebec in 1914, where it was found feeding on radish, turnips, and cabbage.—It is often found associated with the turnip flea-beetle (P. rittata).

The occurrence and danger from Pantomorus fulleri in Italy, A. RAZZAUTI (Bol. Lab. Zool. Gen. e Agr. R. Scuola Sup. Agr. Portici, 7 (1913), pp. 113-124, figs. 7; abs. in Rev. Appl. Ent., 2 (1914), Ser. A, No. 6, pp. 346, 347).—A summarized account of Fuller's rose beetle P. (Aramigus) fulleri, including descriptions of its several stages, geographical distribution, food plants, and methods of control. This pest, first collected in Italy in Ligaria in 1898, has since been found at Leghorn, and at Palermo, Sieily.

The strawberry root weevil (Otiorhynchus ovatus) in British Columbia with notes on other insects attacking strawberry plants in the lower Fraser Valley, R. C. TREHERNE (Canada Expt. Farms Bul. 18 (1914), 2. ser., pp. 44, flgs. 9).—This is a more detailed account of the author's investigations of O. ovatus than that previously noted from another source (E. S. R., 30, p. 58).

Among the other pests upon which brief notes are given are O. sulcatus, which apparently does not occur in the Northwest in sufficient numbers to cause marked injury to strawberries: a lepidopteran (Aristotclia sp.), larvæ of which attack the crowns of strawberry plants, which has been a source of some injury in the vicinity of Vernon; the bronze flea-beetle (Haltica cricta), which was abundant on strawberry leaves at Nelson in 1910; a carabid Harpalus sp., adults of which devour the ripe fruit; wireworms, which are commonly found in a strawberry plantation; the western lined June beetle (Polyphylla decemlineata), which has been reported to be a source of injury; a geometrid (Mesoleuca truncata), the larva of which has been recorded as destructive to the strawberry; cutworms, Scopelosoma tristigmata and the black cutworm; and the western strawberry crown borer (Tyloderma fovcolatum), an account of which has been previously noted (E. S. R., 10, p. 866).

Fourth annual report of the state inspector of apiaries, B. N. Gates (Agr. of Mass., 61 (1913), pp. 269-284, pls. 2).—This is a brief report of the work of apiary inspection during the year. Articles on (1) Soft Candy for Bees. The So-called "Fuller Candy" for Queen Cages, Transportation of Combless Colonies, and Stimulative and General Feeding; and (2) An Inquiry into the Spraying Laws of North America in Their Relation to Beekeeping Interests, are appended.

Bees visiting Helianthus, T. D. A. COCKERELL (Canad. Ent., 46 (1914), No. 12, pp. 409-415).—The author reports upon the bees that visit species of annual and perennial sunflowers of the genus Helianthus, Andrena helianthi being thought to be the most important. It is pointed out that the common sun-

flower, *Helianthus annuus*, is wholly sterile with its own pollen and has to be **v**isited by insects in order to produce seeds, and that presumably the same is true with other species of the genus.

A species of Megastigmus reared from larch seeds, S. Marcovitcii (Canad. Ent., 46 (1914), No. 12, pp. 435-438, figs. 8).—Megastigmus laricis, a chalcidid reared from seeds of the larch. (Larix laricina) at Ithaca, N. Y., in September, 1913, is described as new to science.

The insect galls of Cedar Point and vicinity, P. B. Sears (Ohio Nat., 15 (1914), No. 2, pp. 377-392, figs. 63).—A synonymic list with brief descriptions and pen illustrations of 63 galls, many of which are common throughout Ohio.

Three new Hymenoptera, J. C. Crawford (Inscentor Inscitic Menstruus, 2 (1914), No. 3, pp. 36-38).—Pachyneuron hammari, reared from codling moth material at Roswell, N. Mex.; Cyrtogaster glasgowi, reared from puparia of Brachydeutera argentata at Urban, III.; and Pleurotropis testaccipes, reared from a leaf miner on an undetermined plant at Batesburg, S. C., are described as new.

A revision of the braconid genus Urosigalphus, J. C. Crawford (Insecutor Inscitiæ Menstruus, 2 (1914), No. 2, pp. 22-27).—In his revision of this genus of parasites the author presents a table for the separation of 13 species of which 8 are described as new to science.

Report of field entomologist Fullaway on his expedition to Africa, D. T. Fullaway (Hawaii, Forester and Agr., 11 (1914), No. 12, pp. 349, 350).—A brief statement of the success attained in the introduction of fruit fly parasites into Hawaii.

Some observations on the salivary secretion of the commoner bloodsucking insects and ticks, J. W. Cornwall and W. S. Patton (Indian Jour. Med. Research, 2 (1914), No. 2, pp. 569-593, pls. 2).—A report of studies of a number of hematophagous arthropods.

Tea and citrus mites, A. RUTHERFORD (Trop. Agr. [Ceylon], 42 (1914), No. 3, pp. 225-229).—Notes are presented on Brevipalpus oboratus, a common and widely distributed tea pest; Tetranychus bioculatus, which apparently is the least injurious of the mites attacking tea in Ceylon; and T. mytilaspidis, which the author reports having been recently found on citrus in Ceylon.

Cactus solution as an adhesive in arsenical sprays for insects, M. M. High (U. S. Dept. Agr. Bul. 160 (1915), pp. 20).—In searching for an adhesive for use with arsenicals, the author's attention was directed to the prickly pear (Opuntia lindheimeri) which is used by Mexicans to promote adhesiveness in whitewash. This eactus, which contains a high fluid coutent and is very mucilaginous, is sliced several hours previous to the application and placed in the water or lime mixture.

In the author's control work with the belted cucumber beetle (*Diabrotica balteata*) tests were made of the adhesive action of a cactus solution on Parls green, lead chromate, zinc arsenite (in both paste and powder forms), lead arsenate, ferrons arsenate, and iron arsenite. A comparative test of cactus and whale oil soap as adhesives resulted in favor of the former.

Experience indicates that 15 lbs. of cactus with spines, which is preferable to the spineless, is the proper proportion to use with 50 gal. of water. By the use of cactus solution as an adhesive not only do the arsenicals give better and more lasting results, but considerable expense may be saved through the use of the powdered form. Copper sulphate may be used as a preservative for the cactus solution.

The author's experiments show that the beetle can be best controlled by spraying with zinc arsenite or with Paris green. The other arsenicals employed,

while effecting a control in most cases, did not give as high mortality as these two.

The use of eactus solution is applicable to regions where prickly pear is easily obtainable and for the treatment of insects of related habits, such as the striped and twelve-spotted cucumber beetles, etc.

FOODS-HUMAN NUTRITION.

Text-book of the chemistry, bacteriology, and technology of foods and condiments for students, veterinaries, food chemists, physicians, and pharmacists and for use in technical and agricultural high schools, A. Kossowicz (Lehrbuch der Chemic, Bakteriologie, und Technologie der Nahrungs und Genussmittel für Studierende tierärztlicher, technischer, und landwirtschaftlicher Hochschuten, Nahrungsmittelehemiker, Mediziner, und Pharmazeuten. Berlin: Borntraeger Bros., 1914, pp. VI+557, figs. 225).—As the title implies, this book is designed as a text-book for the study of foods from the standpoints of chemical composition, manufacture, preparation, and preservation. In addition to the chemistry and bacteriology of the subject, the mechanical aspect of food preparation is also considered somewhat at length, and a great many illustrations are given of different machines employed in the food industries.

The most important food materials considered are the following: Meat and meat products, milk and dairy products, fats and oils, cereals and cereal products, fruits and fruit products, sugar, chocolate and chocolate products, and tea, coffee, and other beverages, both alcoholic and nonalcoholic.

Household chemistry, J. Klein (Chemic in Küche und Haus. Leipsic: B. G. Teubner, 1914, 3. ed., pp. VI+136+16).—This book presents briefly the fundamental principles of general chemistry and treats somewhat at length of the chemistry of foods and cooking, together with the biochemistry of fermentation, preservation, and disinfection. There is also a chapter on heating and lighting which discusses the chemistry of these subjects.

The pure food cookbook, MILDRED MADDOCKS (New York: Hearst's International Library Co., 1914, pp. VIII+417, figs. 85).—In addition to a large number of recipes, this book contains sample menus and a chapter on the planning of meals. An introductory chapter by H. W. Wiley, with notes on foods and food values by the same author, is also included. A chapter is devoted to advice regarding the selection and making of coffee.

The physical character of the curd of milk from different breeds.—Curd as an index of the food value of milk.—Studies of the proteid content of milk, S. S. Buckley (Maryland Sta. Bul. 184 (1914), pp. 227-242).—The greater part of this publication consists of a report of an investigation of the protein reactions with precipitating reagents in the case of milks from Holsteins, Ayrshires, Jerseys, and Guernseys. Some comparative tests were also made with milks of other species (human, mule, and goat) and with abnormal cow's milk. A discussion of the relation of this study to the digestion and assimilation of raw milk by infants concludes the report. In this connection the following quotations are of interest:

"Milks may have been found to have been produced under perfect conditions as far as the food of the cow and the proper care of the milk are concerned; both may have been shown to contain normal amounts of the several constituents; in fact, they may have tested alike in the content of fat and other solids, yet the results of feeding it to infants are widely different.

"The breed of the cow may be the only recognizable factor in which a difference [in digestibility] could exist, and yet there has been no measurable difference [in digestibility] could exist, and yet there has been no measurable difference.

ence in the character of the constituents recognized, except the size of the fat globules and the flocculence of the curd.

"The size of the fat globules would not seem to be an important factor in itself, for the reason that in most all cases where an infant has failed to thrive upon a particular milk and is unable to digest and retain it it is possible to give the cream from such milk with satisfactory results. Furthermore, the size of the fat globules in human milk range in size from the smallest found in cow's milk to the largest found in cow's milk, and averages about midway between the Holstein-Ayrshire class and the Jersey-Guernsey class.

"The flocculence of the curd has been claimed for some time by the advocates of the Holstein and Ayrshire breeds of cows to be especially desirable for milks for infant feeding. The results of the work done in connection with the reactions of the proteids in the presence of precipitating solutions confirm the claims of these in regard to the flocculent nature of the curds and in addition show that the milks of these two breeds are not so easily curdled with the natural acid of the stomach as are those of the Jersey and the Guernsey breeds.

"The results of the work done on abnormal milks are not sufficient to draw conclusions from, nevertheless they indicate an important line of observation. It may prove possible by such reactions to determine exactly what period after calving and what time at the end of the lactation period is necessary to elapse before the milk of such cows is proper for food."

Beef frozen for 18 years, G. T. Burrows (Breeder's Gaz., 66 (1914), No. 13, p. 484, fig. 1).—Note is here made of a quarter of beef which was kept frozen for 18 years, and at the end of that time showed no indication of putrefaction. The fibers of the meat on microscopical examination appeared normal, and the meat was consumed without any signs of digestive disturbance—It is stated that one reason why this meat maintained its good condition was that it had not been kept in a chamber in and out of which other beef was passing.

Growth in meat of bacilli causing food poisoning, E. Sacquérée (Compt. Rend. Soc. Biol. [Paris], 75 (1913), No. 34, pp. 490-492).—An experimental study was made of the growth of organisms of the Gärtner type upon the surface of meat as well as of the rapidity with which they penetrated its interior. The growth upon the surface was found to be much the more rapid. At 37° C. the bacilli growth over the surface was found to have spread in 24 hours to a distance of from 10 to 12 cm. from the point of infection, while under the same conditions it penetrated into the interior to a depth of only 4 cm. from the point of infection.

Growth of these organisms on the surface was found to be most favorable when the surrounding temperature was about 37 and when there was little evaporation. On the other hand, very little development was observed when the surrounding temperature was low and when there was considerable evaporation.

The identity of starches of different origin, C. Tanket (Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 19, pp. 1353-1356; abs. in Chem. Zentbl., 1914, II, No. 1, p. 51).—To determine whether or not starches of different origin are identical, the author determined the amounts of amylopectin and amylase present in the starches prepared from cereal grains, legumes, chestnuts, apples, bananas, and potatoes. Since these constituents were present in different proportions and showed unequal solubilities in boiling water, the author concludes that starches of different origin are not of uniform composition.

Variations in gluten, Marchadier and Goujon (Jour. Pharm. et Chim., 7. ser., 10 (1914), No. 5, pp. 191-202).—The author has attempted to account for the curious color changes taking place when flour from wheat is compounded

with that of other grains. Analyses of different grains are given, with particular reference to the glutenin-gliadin ratio. The germination, milling, storage, and temperature are factors affecting the quality and quantity of coagulable gluten, but acidity of the grain is most important in regulating the glutiningliadin ratio.

Maize products as human food, F. Fidanza (Ann. 1g. Sper., n. ser., 24 (1914), No. 3, pp. 507-517).—The results are reported in detail of experiments which tend to show that, considered from the standpoint of the utilization of protein, maize products have an inferior value to those of wheat and other cereals. This inferiority was manifested not only in the case of persons who are unaccustomed to a maize diet but also in the case of those who are accustomed to such a diet.

Food products from the soy bean, H. M. Looms (Amer. Food Jour., 9 (1914), No. 8, pp. 472–475, fig. 1).—The method of preparation of a number of Japanese food products is described, including shoyu or soy sauce, tofu or soy bean curd, soy bean oil, and miso, a fermented product. A table is given showing the chemical composition of these products. The paper is followed by a discussion.

On the occurrence of creatinin in leguminous seeds, K. OSHIMA and M. ARIIZUMI (Jour. Col. Agr. Tohoku Imp. Univ., 6 (1914), No. 2, pp. 17-25).—In these experiments a number of different methods were applied to determine the presence of creatinin in various legumes. It was found to be present in the seeds of the Adzuki bean, kidney bean, and soy bean in small amounts, and in the horse bean and in green peas in even lesser quantities.

Gray honey, C. Reese and J. Drost (Ztschr. Untersuch. Nahr. u. Genussmtl., 28 (1914), No. 3, pp. 150-154).—The properties of this substance are described and some information is given regarding the so-called "sugar-layer," which may develop in honey on long standing.

Recipes for the use of potatoes and potato products in cookery (Ztsehr, Landw, Kammer Schlesien, 18 (1914), No. 38, pp. 1484, 1485).—Notes are given concerning the use of potato flour.

Uses of fruit from domestic science viewpoint, Ava B. MILAM (Ann. Rpt. Oreg. State Hort. Soc., 5 (1914), pp. 79-81).—A brief preliminary note is made of experiments which are being carried out to determine the comparative cooking qualities of different varieties of apples, grapes, pears, etc., at certain seasons of the year.

Recipes for the preparation of simple fruit dishes, M. Pfeifer (Ztschr. Obst u. Gartenbau, 40 (1914), No. 9, pp. 130-133).—Several examples are given to illustrate the manifold possibilities of the fruit compote.

Roselle recipes, P. J. Wester (*Philippine Agr. Rev.* [English Ed.], 7 (1914). No. 5, pp. 239-241).—In this article recipes by E. L. Worcester are given for the preparation of a number of dishes flavored with roselle sirup and roselle jelly. For earlier work see a previous note (E. S. R., 29, p. 566).

Indian chutneys, pickles, and preserves (Calcutta: Thacker, Spink & Co., 1914, pp. 92).—A compilation of recipes.

Salads, sandwiches, and chafing-dish dainties, Janet McK. Hill (Boston: Little, Brown & Co., 1914, rev. ed., pp. XVII+231, pls. 38).—A compilation of selected recipes with hints on serving. Special attention is given to the preparation of decorative dishes.

Rigby's reliable candy teacher (*Topeka*, *Kans.*: Rigby Publishing Co., 1914, 11 ed., pp. XXXI+222, pl. 1).—General directions for candy making, recipes, formulas, and hints regarding the display of candy are contained in this book.

Confectionery (marshmallows), A. McGill (Lab. Inland Rev. Dept. Canada Bul. 292 (1914), pp. 11).—The results are presented of the inspection and

analysis of 93 samples of marshmallows, which were examined especially for their content of sulphurous acid and sulphites, sometimes added to produce the desired whiteness. The quantity of sulphurous acid present in no case exceeded 1 part in 2,000 by weight, which is regarded as harmless to health.

A sanitary code for bottlers (*Pure Products*, 10 (1914), No. 11, pp. 546–549).—The text is given of a code issued by the Agricultural Commission of the State of Ohio for the conduct of places where soft drinks are prepared.

Concerning nickel cooking vessels (*Pure Products*, 10 (1914), No. 11, pp. 543, 544).—This note states that the solubility of nickel varies according to its method of manufacture.

The following figures show the quantities of nickel per square meter of surface dissolved by sulphuric acid: Rolled nickel, 15.5 to 16.9 mg.; cast nickel, 25.5 to 28.8 mg.; electrolytic nickel, 30.6 to 30.8 mg.; drawn nickel, 33.1 to 39.0 mg.; and pure nickel, 61.4 to 65.5 mg.

The diet, its composition, and influence on the health, with special reference to the mineral constituents, R. Berg (Die Nahrungs und Genussmittel, ihre Zusammensetzung und ihr Einfluss auf die Gesundheit, mit besonderer Berücksichitzung der Aschenbestandteile. Dresden: Holze & Pahl, 1913, pp. 60; rev. in Zeutbt. Biochem. u. Biophys., 17 (1914), No. 3-4, p. 159).—This book contains data regarding the ratio of the acid and basic mineral constituents of foods and is based on the theory that the diet should contain more than enough inorganic bases to neutralize the inorganic acids. Some of the data is the result of original work, but the greater part has been compiled from various sources.

The derangement of the skeletal system by a diet poor in phosphorus, M. Masslow (Biochem. Ztschr., 64 (1914), No. 1-3, pp. 106-110).—The results of a microscopical examination of bones strengthen the author's conclusions, drawn from previous work (E. S. R., 30, p. 669), that a deficiency of phosphorous in the diet plays a definite part in pathogenic disturbance of the bones.

The distribution of phosphorus in striated muscle, A. E. Rabbeno (Arch. Farmacol, Sper. e Sci. Aff., 18 (1914), No. 3, pp. 97-106).—From the examination of several samples of strained muscle, from both human and animal sources, the author concludes in part that the inorganic phosphorus makes up about 65 per cent of the total phosphorus content of the muscle. The nucleo portion of organic phosphorus is greater than the portion outside the nucleus.

Maintenance of mice on a diet composed of simple foods, F. RÖHMANN (Biochem. Ztschr., 64 (1914), No. 1-3, pp. 30-62, figs. 23).—A series of experiments was conducted to determine the relative nutritive values of protein containing phosphorus and phosphorus-free protein. A large amount of experimental data is given, from which the following conclusions are drawn.

Phosphorus-containing protein is not absolutely necessary in the diet. Such compounds found in the body cells may be synthetized in the animal organism. Purin bases such as lecithin may be similarly formed.

The relations of vitamins to lipoids, EVELYN A. COOPER (Biochem. Jour., 8 (1914), No. 4, pp. 347-354).—The results are reported of investigations regarding experimental beri-beri from which the conclusion is drawn that vitamins do not enter into the constitution of the lipoids of brain and muscle but may be absorbed by them and stored until needed by the organism. The deleterious effects of lipoid-free diets observed by some workers are attributed by the author to mechanical removal of vitamins by alcohol-ether extractions rather than to a deficiency of lipoids.

Studies of a qualitatively insufficient diet, S. Oseki (Biochem. Ztschr., 65 (1914), No. 1-2, pp. 158-176).—Feeding experiments with laboratory animals

(mice) carried out to contribute to the knowledge of vitamins and lipoids may be summarized as follows:

Rye bread prepared with water was found to have a greater nutritive value than bread prepared from fine wheat flour and water. The nutritive value of the wheat bread was greatly increased and in some instances made to equal that of rye bread by an addition of milk, pressed lees, rye bran, wheat bran, or extracts prepared from army bread. Since these constituents of rye bread, which are necessary for the maintenance of life, dissolve readily in water but can not be extracted with alcohol and ether, they can not be identified with the lipoid-like nutrients of milk.

Study of the diet of laborers in a district of Spain, I. G. COLMENARES (Bol. Agr. Téc. y Econ., 6 (1914), No. 69, pp. 833-838).—The author reports the results of observations regarding the diet of laborers. This diet is found to be deficient in protein, in fat, and in carbohydrates.

[Army rations] (Pure Products, 10 (1914), No. 11, pp. 545, 546).—Notes are given of the minimum daily rations supplied to the French, German, and Belgian soldiers.

Subsistence Supplies Branch [Office of U. S. Quartermaster General] (War Dept. [U. S.], Rpt. Quartermaster Gen., 1914, pp. 12-18).—On the basis of experience some information is given regarding the use of dehydrated vegetables. Field bread, rolling kitchens, cooking outfits for Philippine scouts, and field cooking utensils are discussed. Statements are made regarding the extension of schools for army bakers and cooks.

Brief reference is also made to studies of emergency rations undertaken for the War Department by the Nutrition Investigations of the U. S. Department of Agriculture. It is pointed out that digestion experiments with an emergency ration of which chocolate was a component led to the conclusion that it was not suitable for this purpose. The ration was, therefore, discontinued, and experimental studies are being made with a view to finding a substitute which will fulfill the necessary conditions.

The specific dynamic action of foods, S. Cserna and G. Kelemen (Biochem. Ztschr., 66 (1914), No. 1-3, pp. 63-74).—Intravenous injection into eviscerated animals (dogs) of substances such as urea, sodium chlorid, and dextrose produced an increase in gaseous metabolism. The authors state that this increase can not be due to the increased work of the kidneys or to acceleration of the heart action, as has been suggested by others, since different substances injected in the same quantity of liquid produced this increase in different degrees. In the light of these experiments it also appeared that the gaseous metabolism is not proportionately increased with the work of the intestines. The authors believe that the increased metabolism produced by these substances depends upon their stimulative action on the cells whereby their metabolism of matter and energy is increased.

The influence of the spleen in nutrition, C. RICHET (Jour. Physiol. et Path. Gén., 15 (1913), No. 3, pp. 579-583; abs. in Hyg. Rundschau, 24 (1914), No. 9, p. 530).—According to the author's observations, laboratory animals (dogs) with the spleen removed required more food to maintain unchanged weight than normal animals. Therefore he concludes that the spleen plays a very important part in nutrition, aiding in the complete utilization of nutritive material.

The influence of early removal of the thyroid and parathyroid glands upon nitrogenous metabolism in the sheep, A. Hunter (Quart. Jour. Expt. Physiol., 8 (1914), No. 1, pp. 23-32).—The following conclusions were drawn by the author from the results of a study of three laboratory animals (sheep) from which the thyroid and parathyroid glands had been removed:

"These animals excrete during a fast rather more nitrogen and rather more purin derivatives, in relation at any rate to body weight, than do normal animals; are liable, although by no means certain, to succumb very early to the effects of inanition; may fail to exhibit such signs of hunger acidosis as a high output of ammonia, and the elimination of aceto-acetic acid; excrete while fasting urine which is generally alkaline and never acid; invariably react to the withdrawal of food by the excretion of creatin in excess of creatinin; exhibit in the relations of the purin catabolites no evidence of diminished oxidative power; and have a degree of sugar tolerance which is almost certainly above the normal."

The intestinal absorption of fats, K. Nakashima (*Pflüger's Arch. Physiol.*, 158 (1914). No. 6-8, pp. 288-306).—The mechanism of fat digestion was studied in a series of normal feeding and injection experiments carried out with laboratory animals (mice). An examination of the blood after the injection of milk fat into the rectum and large intestine failed to indicate any absorption of the fat by the blood. Milk fat fed normally per mouth, however, appeared in the blood.

Absorption of fat in the peritoneum, K. Nakashima (Pflüger's Arch. Physiol., 158 (1914), No. 6-8, pp. 807-342).—In extending the work noted above, experiments were carried out in which milk fat was injected into the peritoneum. From subsequent examinations of the blood the following conclusions were drawn:

The fat is taken in corpuscular form from the peritoneum into the blood stream, the resorption taking place both in the case of cold- and warm-blooded animals. Casein is absorbed still more easily than the fat, but both appear in the blood within 20 minutes after ingestion and traces of the fat remain for 24 hours. Lecithin is absorbed slowly. Resorption of fat from the peritoneum takes place through the lymphatics.

The relation between energy metabolism and protein metabolism under fasting conditions, P. Hári (Biochem. Ztsehr., 66 (1914), No. 1-3, pp. 1-19).—The results of a large number of experiments with fasting dogs are reported in which the heat production was measured both directly and indirectly. From these results the author draws the following conclusions:

The energy metabolism computed per square meter of body surface at different temperatures varies during the first eight days of the fasting period between 700 and 1,000 kilogram-calories. This value is independent of the body weight, but varies directly with the amount of body protein. The increase of energy production depends not only upon increased protein consumption but also upon a greater combination of fat, which could be designated as the specific dynamic action of the body protein. The suggestion is offered that possibly the decomposition products of body protein in some way accelerate the combustion of the fat.

The total energy requirement in disease as determined by calorimetric observations, E. F. Du Bois (Jour. Amer. Med. .; 880c., 63 (1914), No. 10, pp. 827-830, figs. 5).—Results which are of general interest are here reported of a series of experiments carried out to determine the influence of a number of diseases upon metabolism. For this purpose a respiration calorimeter of the Atwater-Rosa type, and equipped with a bed, was used. The fact is emphasized "that the nutrition of a patient depends absolutely on the relationship between his energy production and his food supply. If the organism fails to obtain food from without, it will draw on its own glycogen stores, fat depots, and supplies of body protein."

A contribution to the study of experimental beri-beri, R. McCarrison (Indian Jour. Med. Research, 2 (1914), No. 1, pp. 369-374, pl. 1).—In a labora-

tory study of experimental beri-beri in pigeons, the presence of certain bacteria was noted in the internal organs of the animals developing the disease. Inoculation of the animals with cultures of this organism produced symptoms which were indistinguishable clinically from typical polyneuritis gallinarum.

The treatment and prevention of pellagra, J. Goldberger, C. H. Waring, and D. G. Willets (Pub. Bealth Rpts. [U. 8.], 29 (1914), No. 43, pp. 2821-2825).—An extended study of this disease tends to strengthen the conclusion that it is neither infectious nor contagious, but essentially due to some fault in the diet in which the proportion of animal or leguminous protein is abnormally small and the nonlegiminous vegetable component abnormally large. Experience shows that pellegra does not develop among those who consume a mixed, well-balanced, and varied diet. The prevention of the disease depends upon the substitution of a mixed, well-balanced diet for the one-sided diet. The most important dietary change recommended is an increased use of milk, eggs, lean meat, and legumes, either fresh or dried beans and peas (not canned). A greater use of dried legumes, as a cheap and readily variable source of protein, is urged.

Protein metabolism in fever and during work—studies regarding the nitrogen minimum, R. Kocher (Deut. Arch. Klin. Med., 115 (1914), No. 1-2, pp. 82-123; abs. in Zentbl. Biochem. u. Biophys., 17 (1914), No. 5-6, p. 178).— Observations upon fever patients who were given a diet which supplied 80 calories per kilogram of body weight showed the nitrogen metabolism to be excessive. With a decrease in temperature to normal the nitrogen minimum was reached. A corresponding decrease in the values of uric acid, creatinin, phosphorus, and sulphur was also noted. The author suggests that the rise in body temperature during fever may be caused by a specific action of the fever on the cell protoplasm.

The influence of the high-calorie diet on the respiratory exchanges in typhoid fever, W. Coleman and E. F. Du Bois (Arch. Int. Med., 14 (1914), No. 2, pp. 168-209, figs. 4).—From the large amount of experimental data obtained in 134 observations with a universal respiration apparatus upon a number of patients, the conclusions drawn are in part as follows:

"The large amount of food administered exhibits little or no specific dynamic action, thus removing the chief theoretical objection to the use of a liberal diet in typhoid fever. In the high-calorie cases approximately 10 per cent must be added to cover the increase in metabolism caused by bodily exertion incident to moving about the bed. The theoretical requirement must be exceeded by from 50 to 110 per cent in order to bring the patient into nitrogen and weight equilibrium. The fate of the excess has not yet been discovered."

Studies regarding the possibility of an inversion of the daily temperature curve of man, O. Polimanti (Zischr. Allg. Physiol., 16 (1914), No. 3-4, pp. 506-512, figs. 2).—Observations of the variations, during the 24-hour cycle, in body temperature of a man, who for a period of six years had worked nights and slept days, showed no tendency for a reversion of the normal temperature curve. The temperature curve in this case was essentially the same as that of a man of normal habits.

The effect on man of winter climbing in high altitudes, N. Zuntz (Separate from Ztschr, Balneol., Klimat. u. Kurort Hyg., 6 (1913-14). No. 18, pp. 3).—
The author took the opportunity presented by a walking trip up the Brocken during the winter of 1913 to collect data regarding the effect of severe exercise in cold weather at high altitude. Thirty-one members making the trip filled in questionnaires regarding the effects of the exercise on muscles, breathing, heart action, skin, etc. The weather on the day of the climb was cold and windy, and during the descent there was a severe snowstorm.

Data are given regarding the effects of the exertion on men of different ages and previous training, from which the author concludes that even very severe and unusual body exertion combined with great demands on the heat regulating machinery of the body does not as a rule produce any deleterious results. On the contrary, it induces good sleep and a feeling of refreshment even in persons little used to walking. The men in good training and general condition undoubtedly had the advantage during the ascent, but the final results were favorable also for those to whom the ascent was difficult or even painful.

The study seems to prove that to include considerable muscular exertion in a winter vacation trip raises the general tone of the body by strengthening the heart and improving the vasomotor activity.

A method for the study of the periods of rest and activity of laboratory animals, J. S. SZYMANSKI (*Pflüger's Arch. Physiol.*, 158 (1914), No. 6-8, pp. 343-384, figs. 35).—A detailed description is given of a delicate modification of the kymograph which the author employed in the study of a number of small laboratory animals (such as goldfish, canary birds, etc.) during day and night. A diagrammatic explanation of the modification is given.

On the respiratory exchange in fresh water fish.—I, On brown trout, J. A. GARDNER and CONSTANCE LEETHAM (*Biochem. Jour.*, 8 (1914), No. 4, pp. 374–390, figs. 2).—Detailed descriptions are given of apparatus and experimental technique. The data reported may be summarized as follows:

Oxygen absorption was approximately proportional to the body weight at a given temperature and yielded a respiratory quotient of about 0.8. The considerably lower respiratory quotient noted at low temperatures is explained by the authors on the theory that at low temperatures the animals are in a state of hibernation or starvation and live on their fat, partially converting it into glycogen and sugar.

Laboratory experiments with air, F. S. Lee (Jour. Amer. Med. Assoc., 63 (1914), No. 19, pp. 1625–1628).—In this summary of the contributions of his laboratory to the knowledge of air in relation to ventilation problems the experiments being carried out by the New York State Commission on Ventilation are very briefly described.

In these experiments one group of laboratory animals (cats) was kept for a period of 6 hours at a temperature of 21° C. (70° F.) and in an atmosphere of 54 per cent humidity. Another group of animals was kept under conditions of humidity as high as 89 per cent at temperatures as high as 33°. Under these conditions, which were comparable with those of a hot and humid summer day, the body temperature rose on an average of 0.5° during the 6-hour period. At the end of this time stimulation of certain muscles of the animals showed that they were able to perform only an amount of work which was 14, 18, and 26 per cent less than was the case with animals of the first group which had been kept under more favorable atmospheric conditions. A diminution of 13 per cent in the blood sugar was also noted. Further experiments are being carried on along this line.

[Report of the work of the] nutrition laboratory, F. G. BENEDICT (Carnegie Inst. Washington Year Book, 12 (1913), pp. 241-254).—Notes of changes and improvements of equipment, brief general descriptions of the various metabolism experiments in progress, and brief reviews of the publications issued during the year 1913 are given.

International catalogue of scientific literature. Q—Physiology. QR—Serum physiology (Internat. Cat. Sei. Lit., 10 (1914), pp. VIII+1155, V+182+36).—This volume, like the preceding ones (E. S. R., 20, p. 1168), contains references to scientific articles on subjects regarding general physiology, including among other subjects those of respiration, heat production, digestion, absorption, and metabolism.

ANIMAL PRODUCTION.

[Animal production], von Ollecui (Jahresber, Landw., 28 (1913), pp. XXVI-XLI, 299-496).—A compilation of abstracts of German articles on various phases of animal production and dairying published during 1913 and previously reported from other sources.

Record of proceedings of the annual meeting, December, 1913, of the American Society of Animal Production (Amer. Soc. Anim. Prod. Proc. 1913, pp. 39, figs. 6).—This gives the proceedings of the annual meeting held in Chicago, December 3, 1913, previously referred to (E. S. R., 30, p. 99).

Acidosis in omnivora and herbivora and its relation to protein storage, II. Steenbock, V. E. Nelson, and E. B. Hart (Jour. Biol. Chem., 19 (1914), No. 3, pp. 399-419).—The authors summarize the results of their studies as follows:

"Acid rations fed to swine (omnivora) or calves (herbivora) occasion a rise in urinary ammonia with a compensative fall in output of urea. Presumably on a normal level of protein intake a part of the ammonia produced either in the intestine or liver combines with acids and is excreted as the salts of these acids. This power to help maintain neutrality by the production or use of ammonia is apparently very general in all mammals. Ammonia production, under conditions of exogenous protein metabolism, does not occasion an increased nitrogen excretion or an interference with protein storage.

"In herbivora (calves) approximate endogenous nitrogen metabolism, accompanied by mineral acid ingestion, likewise occasions a rise in urinary ammonia, but does not, on the level of acid used, cause a rise in protein catabolism, as has been observed with dogs and swine. This may be due in this experiment to a greater dilution of the ammonium salts incident to a large consumption of water by this class of animals.

"Data are also given on calcium and phosphorus metabolism during both neutral and acid periods of low nitrogen intake, as well as on a period of high nitrogen intake. Very probably the skeleton was not drawn upon for calcium during the period of lowest acid ingestion. Only on a high acid ingestion did it appear probable that decalcification of the bones began and then only a withdrawal of calcium carbonate.

"From the records submitted on growth and reproduction, it is believed that natural acid rations, if otherwise satisfactory, are as effective for growth or reproduction as those of basic character. However, until it has been shown conclusively that less vigorous individuals will tolerate acid rations with perfect impunity, we are not warranted in making too sweeping conclusions."

The value of acorns, horse chestnuts, and beech mast as food for stock (Jour. Bd. Agr. [London], 21 (1914), No. 6, pp. 511-528).—A general summary of material collected from other sources on the value of these products for stock.

Calcium phosphate in the rations of domestic animals, J. Denayre (Handel. Vlaamsch Natuur en Geneesk. Cong., 17 (1913), pp. 218-222).—Data are cited tending to show that the addition of calcium phosphate to the ration increases the height, weight, and general conformation of young growing horses.

The feeding value of pastures.—An experiment with different grass-seed mixtures, J. Hendrick and W. M. Findlay (*Trans. Highland and Agr. Soc. Scot.*, 5. ser., 26 (1914), pp. 195-211).—Four pasture lots were calculated to contain 59.3, 64.5, 67.1, and 40 per cent, respectively, of white clover. In addition lot 1 had 37.9 per cent perennial rye grass; lot 2, 25.8 per cent perennial rye grass and approximately 9 per cent cocksfoot and timothy; lot 3, 19.5 per cent cocksfoot and 10.4 per cent timothy; and lot 4, 18.7 per cent cocksfoot, 11.2 per cent timothy, and 20.9 per cent tall oat grass.

During 1912 these plats were pastured with sheep. The average weight of sheep carried per acre on the several plats was 440, 460, 489, and 441 lbs., respectively, and the average increase per sheep in 16 weeks was 43.9, 45.2, 51.5, and 42.6 lbs.

During 1913 these plats were pastured to eattle in the early part of the season and sheep in the fall. The average increase per acre for the 3-months' cattle feeding was 233, 271, 254, and 295 lbs., respectively. The average weight of sheep carried per acre was 239, 189, 184, and 188 lbs., and the average increase per sheep during 10 weeks pasturing was 11.5, 16.8, 15, and 12.6 lbs., respectively. The total value of produce per acre for the one year of haying and two years of pasturing was £15 68, 11d., £16 58, 1d., £16 7d., and £14 168, 7d.

The results obtained from these plats for the three years show, as a whole, that a heavy seeding with rye grass, such as was given plat 1, is not superior to a lighter seeding, such as was given plat 2, or to a mixture without rye grass, such as that of plat 3.

Chemical composition of moor hay causing excessive licking in cattle, H. von Feilitzen (Svenska Mosskulturför, Tidskr., 28 (1914), No. 2, pp. 155–161; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases, 5 (1914), No. 8, pp. 1002, 1003).—Samples of moor hay which caused an excessive desire to lick in cattle were analyzed and found to contain a larger quantity of sodium and chlorin than other hays, thus no doubt furnishing salt desired by the cattle.

Modern silage methods, W. L. Wright (Salem, Ohio: The Silver Manufacturing Co., 1914, 10. cd. rev., pp. 264, figs. 77).—General information on methods of ensiling crops and their feeding to farm animals.

The ensiling of beet tops with lactic acid bacteria, D. MEYER (Landw. Wehnschr. Sachsen, 16 (1914), No. 26, pp. 231, 232).—In experiments in which beet tops were ensiled for 160 days, with and without the use of a lactic acid culture, it was found that the loss of nutrients was in all eases greater in that material ensiled without the use of the culture than that to which it was added. The addition of the culture improved the aroma and palatability of the silage.

The ensiling of potatoes with a lactic acid culture, D. MEYER (Landw. Welmschr. Sachsen, 16 (1914), No. 12, pp. 106, 107).—It is stated that potatoes may be ensiled with less fermentation loss by the use of lactic acid culture. It is estimated that the loss in dry matter is 4.9 per cent, in protein none, in nitrogen-free matter 5.6 per cent, and in fiber 21.8 per cent. The ferment used for this purpose is Bacillus delbrücki in the case of steamed potatoes, and for raw potatoes and roots B. cucumeris fermentati. The ensiled product is high in sugar content and is valuable for all kinds of stock.

Ensiling potatoes (*Ztschr. Landw. Kammer Schlesien*, 18 (1914), Nos. 38, pp. 1485, 1486; 39, pp. 1505, 1506).—Directions are given for the ensiling of both raw and cooked potatoes. A lactic acid culture is added to hasten the fermentation process. It is stated that horses, cattle, and sheep can use 40 kg. of this material per 1.000 kg. live weight per day, while fattening hogs use a smaller quantity.

The utilization of marc for the feeding of cattle, L. Degrully (*Prog. Agr. et Vit.* (*Ed. l'Est-Centre*), 35 (1914), No. 37, pp. 300-303).—A summary of data based largely on the work of Fabre previously noted (E. S. R., 21, p. 667). It is suggested that from 10 to 12 kg. per day may be fed to horses and mules together with bran and a small quantity of water, 20 to 25 kg. to cattle, 5 to 6 kg. to sheep, and 5 to 10 kg. to swine.

Molasses and molasses feeds, J. E. Halligan (Baton Rouge, La.: Bd. Agr. and Immigr. [1914], pp. 2-12, fig. 1).—An account of the composition and feeding value of cane and sugar-beet molasses, and of various molasses-mixed feeds.

There are also included analyses of rice polish, rice bran, rice straw, and rice hulls, together with suggestive rations containing rice products for fattening cattle, dairy cows, hogs, mules, and horses.

Commercial feeding stuffs of Pennsylvania in 1913; their chemical and microscopical examination, J. W. Kellog (Penn. Dept. Agr. Bul. 249 (1913), pp. 189).—Analyses are given of the following feeding stuffs: Cotton-seed meal, linseed meal, dried brewers grains, gluten feed, middlings, molasses feeds, dried beet pulp, corn chop, beef scrap, malt sprouts, buckwheat products, rye products, alfalfa meal, and various mixed and proprietary feeds.

Breeds of beef cattle, W. F. Ward (U. 8. Dept. Agr., Farmers' Bul. 612 (1915), pp. 23, figs. 18).—This bulletin is a discussion of the breed characteristics and utility value of the several breeds of beef and of dual-purpose cattle.

The inheritance of twin calving in cattle, E. Unlmann (Deut. Landw. Tierzucht, 18 (1914), No. 14, pp. 163, 164).—In commenting on the inheritance of twin calving in cattle, an instance is given in which a cow gave birth to twins. In the third generation, of the four heifers born, two gave birth to six pairs of twins, and in the fourth generation two pairs of twins were born.

Corn silage compared with hulls for fattening steers. E. R. LLOYD (*Mississippi Sta. Bul. 167 (1914)*, pp. 3–8).—Four lots of six 4 to 5-year-old native grade steers were fed 142 days, beginning December 1, as follows: Lots 1 and 2, cotton-seed meal, Johnson grass hay, and corn silage; lots 3 and 4, cotton-seed meal. Johnson grass hay, and cotton-seed hulls. Lots 1 and 3 were confined under shelter, lots 2 and 4 had the run of the paddock. The average daily gains per head were 0.77, 1.1, 1.13, and 1.38 lbs., respectively; the shrink in shipping 4.65, 4.65, 5.42, and 5.42 per cent; the cost per pound of gain 18.81, 11.12, 14.06, and 14.06 ets.; the dressing percentage 59.32, 59.32, 59.01, and 59.01 per cent; and the profit per steer (manure not included) \$12.25, \$15.87, \$18.92, and \$22.07.

The manure from the silage-fed steers analyzed as follows: Moisture 74.78 per cent, nitrogen 0.69, potash 0.76, and phosphoric acid 0.63; that from the hull-fed steers, 78.5, 0.57, 0.61, and 0.38 per cent, respectively. That from the former was estimated to be worth \$4.32 per ton and that from the latter \$5.41 per ton.

Two lots of twelve 4 to 5-year-old steers of grade Jersey blood were fed silage and cotton-seed meal and hulls and cotton-seed meal, respectively. The average daily gains per head were 1 and 1.19 lbs.; shrinkage in shipping, 3.23 and 3.58 per cent; cost per pound of gain, 13.14 and 12.38 cts.; dressing percentage, 58.05 and 58.4 per cent; and profit per steer, \$18.42 and \$19.50, respectively.

The feeding and care of dairy calves (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 19, pp. 4).—Popular suggestions on calf feeding, with special reference to cotton-belt conditions.

Sheep grazing on ditches infested with Johnson grass, F. W. Wilson (Arizona Sta. Rpt. 1913, pp. 268, 269).—From experiments conducted in cooperation with the U. S. Reclamation Service it was found that the grazing of sheep on irrigation ditches infested with Johnson grass lessened the stand of grass; the ditch banks were well packed; the gopher holes and gophers seemingly had disappeared; the sheep had been maintained; the expense of controlling the seeding of Johnson grass was cut to a minimum; and the cost of ditch cleaning was decreased.

Producing sheep on southern farms (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Nov. 30, pp. 3).—General suggestions are given.

Swine investigations, F. C. MINKLER (New Jersey Sta. Rpt. 1913, pp. 181-199, pls. 5; Circ. 40 (1914), pp. 3-21, pls. 5).—This treats of the breeding, feeding, care, and management of swine under New Jersey conditions.

In trials to determine the adaptability of alfalfa for pasturing and growing swine, it was found that $2\frac{1}{2}$ acres of alfalfa, not in average condition, furnished forage for 10 head of brood sows and 79 pigs from May 1 to October 1. The sows suckling pigs were fed in addition a ration made up as follows: Corn meal, 100 lbs.; taukage, 12; wheat bran, 10; and oil meal, 4. The pigs were fed limited quantities of skim milk and started on a grain mixture of red dog flour, 100 lbs.; crushed oats, 100; and tankage, 10, with a small quantity of soaked shelled corn. The sows gained slightly in total weight during the season, while the pigs averaged gains of 1.12 lbs. per day from birth until removed to the fattening pens. Without allowing for the hay harvested, the maintenance of the 10 brood sows, and deducting the cost of grain and value of the milk fed, the alfalfa was responsible for approximately 460 lbs, of pork per acre.

Two lots of 7 148-lb. fall shoats each were fed for 30 days beginning May 1 as follows: Lot 1, corn meal and steamed kidney-bean meal, with alfalfa pasture; lot 2, corn meal and bean meal, with skim milk. Lot 1 made an average daily gain per head of 1.63 lbs., lot 2, 1.14. The cost per pound of gain was, for lot 1, 4.3 cts., for lot 2, 7.1 cts. On this basis the forage value of the alfalfa eaten was estimated to be \$21 per acre per month. The alfalfa-fed pigs, which were in a later experiment confined in a dry pen, continued to make more rapid gains than those of lot 2.

Ten 112-lb. pigs were turned into a half-acre of corn to hog down. They cleaned up the plat in 16 days, making an average daily gain per head of 2.27 lbs. Rape and red clover had previously been seeded in the corn and furnished forage for the pigs. On this basis the corn was estimated to be worth \$68.20 per acre.

Six lots of 2 pigs each, weighing approximately 200 lbs., were selected for use in an experiment to determine the palatability and feed value of the refuse product known as garbage tankage. They were fed for 40 days as follows: Lot 1, corn meal and skim milk, 10:25; lot 2, corn meal, molasses, and skim milk, 6:5:25; lot 3, corn meal, molasses, and garbage tankage, 4:2:9; lot 4, corn meal, garbage tankage, and skim milk, 4:9:18; lot 5, corn meal, molasses, garbage tankage, and skim milk, 4:2:9:18; and lot 6, corn meal, garbage tankage, and molasses, 4:8:3. It was necessary to neutralize the acid condition found in the garbage tankage by means of bicarbonate of soda or lime water. The average daily gains per head for the respective lots were 1.72 and 1.5, 1.37 and 1.57, 1.37 and 1.57, 1.1 and 2, 1.4 and 1.72, and 1.65 and 1.64 lbs.; the cost per pound of gain, 7.7, 7.5, 4.2, 5.7, 5.6, and 3.5 cts. The garbage tankage product analyzed as follows: Moisture, 61 per cent, protein, 8.13; carbohydrates, 25.06; and ash, 5.81. Rations for swine are suggested.

Swine-feeding experiments with heated and unheated skim milk and with dried yeast, Klein (Milchw. Zentbl., 43 (1914), No. 14, pp. 381-384).—In these experiments with 7-week-old pigs it was demonstrated that heated skim milk fed in addition to potato flakes and barley bran slightly increased the daily gains during a 12-week period over pigs fed unheated milk, while with pigs fed a similar ration, but in which a portion of the unheated milk was replaced by dried yeast, the daily gains were materially lower.

Fattening pigs on cassava, A. Gouin and P. Andouard (Bul. Soc. Nat. Agr. France, 74 (1914), No. 4, pp. 481-483).—It was demonstrated that in the case of pigs fed milk in addition to cassava it took only 3 lbs. of cassava to produce

a gain in live weight of 1 lb. On substituting for the milk ration 1.1 lbs, of rice gluten and 2½ oz, of bone meal, which are estimated to be the equivalent in nutrients of 1 gal, of separated milk, there was required to produce a gain of 1 lb. live weight only 2.9 lbs, of cassava. While in former experiments (E. S. R., 30, p. 174) the cassava had been fed to the pigs in slices, cooked and crushed, in these experiments it was fed raw, although chopped fine.

How southern farmers may get a start in pig raising (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Nov. 25, pp. 4).—General suggestions are given.

Horse and mule raising in the South (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Nov. 25, pp. 4).—General suggestions are given.

Poultry production, W. A. LIPPINCOTT (*Philadelphia: Lea & Febiger, 1914*, pp. VIII+17-476, pl. 1, figs. 205).—This deals with the breeding, feeding, care, and management of poultry, together with a chapter on preparing poultry products for consumption.

Suggestions on poultry raising for the southern farmer (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Nov. 30, pp. 4).

Report of the poultry husbandman, H. R. Lewis and A. L. Clark (New Jersey Stas. Rpt. 1913, pp. 211–228, 234–259, 271–276, 279–290, pts. 18).—A test made in April to determine the efficiency of a 3.000-egg capacity incubator gave a percentage of hatch of fertile eggs of 77.4, and a percentage in July of 85. Comparing compartments run dry with those run wet it was observed that the latter gave a much higher percentage of hatch as well as an increase in the weight of the chicks, the average weight for the dry being 1.2 oz. and for the wet 1.25 oz.

Four brooders of 100 week-old chicks each were fed for nine weeks, two lots receiving a regular chick ration and the two other lots receiving in addition all the sour skim milk they would consume. The first two brooders made a total gain of 48.62 lbs. and 42.35 lbs., and the mortality was 71 and 73, respectively, while the last two brooders made a total gain of 82.22 and 81.94 lbs., and the mortality was 28 and 28, respectively. It was found to require 3.6 qt. of skim milk to produce a pound of body weight. It is stated that the skim milk-fed chicks represented a more uniform flock than those not so fed. It is thought that skim milk has the power to kill the organisms which cause many poultry diseases, the bacilli being destroyed by the dilute acid of the sour milk.

A brief discussion of the ash and protein factor in poultry feeding, previously reported from another source (E. S. R., 31, p. 568), is given.

The gasoline colony brooder, outdoor lamp-heated brooder, adaptable hovers, the underneath-pipe system, and the overhead-pipe system of brooders are described. It is thought that for the general farm flock the colony brooders or adjustable hovers are best, while for the egg farmer either of these two methods is suitable, or either of the pipe systems in a long house.

In trials with three lots of Leghorn pullets, hatched February 26, April 8, and June 10, respectively, the yearly egg production was 140, 180, and 95 eggs, the feed cost per bird \$1.32, \$1.64, and \$1.25, and the profit per bird above feed \$1.98, \$2.99, and \$1.53, respectively. It was found that soy beans would produce a continuous supply of succulent green feed from August 15 until November, and that owing to their luxuriant growth they produced a liberal amount of shade for the growing chickens. The soy-bean pods were not eaten by the birds, thus probably making it possible to reseed by disking and rolling. The value of mangels as a winter feed for poultry is discussed. The lower leaves of the mangels were slipped three times during the summer and furnished a large amount of green material.

One lot of hens fed for 12 months on a ration consisting of 25 per cent of meat gave an average yearly egg production per bird of 140 eggs, the feed per bird costing \$1.32, and the profit per bird above feed being \$1.98, while another lot fed a similar ration with 10 per cent meat scrap gave an average of 96.7 eggs per bird, costing \$1.27 for feed and yielding a profit of \$1.10 per bird.

It has been observed that a close relation exists between the degree of vigor present in the individuals at breeding time and the vigor of the offspring. Natural vigor may be decreased and increased in young stock by care, feeding, and management while it is growing. Layers and breeders, as well as male birds, are usually lacking in vigor during long periods of excessively hot weather and after periods of continuous heavy laying or intensive use in the breeding pen. Some of the characteristics by which the vigor and vitality of an individual may be judged are the color of the comb, the brightness of the eyes, the strength of the beak, the breadth of the back, the depth of the body, color of the shanks and skin, and the activity of the individual.

An account is given of a White Leghorn hen which yielded in her first year's production 246 eggs weighing 29.5 lbs. She consumed 118.5 lbs. of feed, or 92 lbs. of dry matter, costing \$1.79 and yielded a net profit of \$4.72. During the second year this hen laid 221 eggs weighing 21.6 lbs., or a total of 467 eggs in 730 days. It is said that this hen is one of 20 birds which are the product of definite breeding for high fecundity and whose average yearly production for the first season's laying is over 190 eggs.

The results attendant upon special mating indicate that it is through the male progeny primarily that the egg-producing propensities of any given female are transmitted.

In crossbreeding experiments the occurrence of barred chicks from a supposedly pure-bred White Leghorn male of known breeding is noted. These barred pullets show throughout the Leghorn carriage, and nearly all of the Leghorn characteristics are present with the exception of the plumage pattern.

With a view to determining the mode of inheritance of common variable factors in different breeds, namely, plumage pattern, color of ear lobe, shank, egg, beak, and feet, body shape and shank feathering, reciprocal crosses were made between standard-bred White Leghorns and Black Langshans. In the F₁ generation nothing but white birds were obtained, none of which, however, were pure white. No barred feathers were apparent, but black feathers were quite common. It appeared from an analysis of the F₁ generation that in "the case of shank and eye color, the factor of sex limitation was present; the female progeny inherits from the paternal parent only, while in the ease of shank feathering the presence of this character is in each case dominant over its absence, no sex limitation being apparent."

A crossbreeding experiment with Muscovy ducks, which produce eggs requiring five weeks of ineubation to hatch, with Pekin ducks, whose eggs hatch in four weeks, is reported. The eggs from the Pekin ducks and a Muscovy drake required about two days longer than the pure-bred Pekin ducks for hatching, while the eggs from Muscovy ducks and a Pekin drake were thought to require nearly the full five weeks. All of the 30 ducklings hatched from White Pekin females and a White Muscovy male were nearly black in color, resembling quite closely that of the colored Muscovys. The young hybrid ducks seemed to be equally as vigorous as the pure-bred ducks of either kind. They grew faster, however, than the young ducks of either pure variety.

"The crossbred ducklings presented much the same appearance as did the Muscovy ducklings, there being more meat in proportion to the total weight of

the carcass than on the Pekins. They both had a bright yellow skin and the breast was well covered with meat. The unevenness in size, which is always present with Muscovy ducks in respect to the sexes, was not so apparent with the hybrid ducklings. . . . As the hybrid ducks matured almost no difference was apparent between them as indicating one sex or another. The Pekins' characteristic sex features are the curled feathers upon the tail and the peculiar voice. The characteristic sex features of the Muscovys are principally those of size. With the hybrids no curled tail feathers appeared; in size all remained quite equal, and the voice seemed to be much like that of the Muscovys. Upon examination only two of the hybrid ducks could be found that were apparently males; these two in size and other outward appearances were almost identical with the rest. All of the rest but one seemed to have both male and female organs. One seemed to show genuine female characteristics, and the hermaphroditic characters were not present."

Records kept of nine breeds give for the White Leghorn breed a total percentage of the theoretical production for the year of 31.37, for the Rhode Island Red 29.36, for the Barred Plymouth Rock 27.06, for the Buff Orpington 25.17, Black Langshan 22.29, White Orpington 20.33, White Wyandottes 29.44 (eight months), White Plymouth Rock 22.96 (nine months), and the Light Brahma 12.72 (three months). The average percentage of the theoretical production by months was as follows: November, 1912, 5.65; December, 14.1; January, 1913, 20.28; February, 25.66; March, 41.61; April, 49.72; May, 48.63; June, 42.68; July, 42.69; August, 29.22; September, 18.49; and October, 9.

Tests were made to determine the efficiency of the parcel-post method of shipping eggs. It was found that the cost of shipping eggs was in all cases less than shipping by express, and proportionately much less in near-by than in long hauls. Of the shipments 20 per cent arrived in excellent condition, 40 per cent had some eggs cracked, and 40 per cent one or more completely broken. It seemed to be a question of care in handling rather than of kind of package. It is concluded that parcel post does not offer a reliable method of shipping eggs for hatching or for table purposes and that the violent shaking to which the eggs are subjected in some cases caused a rupture of the shell membrane and destroyed their hatching power.

Poultry rations and methods of feeding, H. R. Lewis (New Jersey Stas. Circ. 39, pp. 3-8; Rpt. 1913, pp. 228-233).—A reprint of a portion of Bulletin 265, previously noted (E. S. R., 31, p. 568), in which rations for laying hens, chicks, and broilers are suggested.

The establishment of a new breed of chickens on the basis of Mendelism, A. Hink (Deut. Tierärztl. Wehnschr., 22 (1914), No. 26, pp. 409, 410).—Experiments are reported in which Wyandottes and an Italian breed were crossed for several generations, resulting in the formation of a breed having a partridge color, a small rose comb, a vigorous constitution, good laying qualities, and other desirable characteristics. From a study of the rose-comb characteristic it was evident that inheritance followed the ordinary Mendelian rule of inheritance.

On inheritance of weight in poultry, R. C. Punnett and P. G. Bailer (Jour. Genetics, 4 (1914), No. 1, pp. 23-39, pls. 2. figs. 9).—The two breeds selected for these breeding experiments were the Gold-penciled Hamburgh and the Silver Sebright Bantam, the object being to learn something about the transmission of weight in poultry. It is concluded that "the facts of breeding offer a clear indication that weight may depend upon the presence or absence of definite genetic factors segregating from one another in gametogenesis on lines with which students of these matters are already familiar." A scheme is sug-

gested by which the phenomena observed in these experiments may be interpreted in terms of genetic factors,

Size inheritance in rabbits, E. C. Macdowell (Carnegic Inst. Washington Pub. 196 (1914), pp. 55, figs. 9).—The author explains the theory and gives examples of multiple factors. In experimental work upon rabbits in which comparatively small and large races were crossed a study was made of skeletal measurements and of adult weight, from which observations it was concluded that "whether on the basis of the comparison of the ranges of litters of the first filial generation with those of their corresponding back crosses, or whether on the basis of the relative variability of the two generations as shown by the standard deviations of the coefficients of size, or by the distribution of frequencies in relation to the parents or grandparents, or, finally, by their body weights, there is found a consistently greater diversity of sizes in the back cross than in the first hybrid generation. Characters occur among the second generation that are smaller than the corresponding characters in the small parent; others that are above the modes of the first generation large parents."

The general law is stated as follows: "The second generation of a size cross shows greater diversity than does the first generation or the parental lines. Size characters that are inherited in a Mendelian fashion are included in the above statement."

An extensive bibliography is included, and a prefatory note and appendix by W. E. Castle.

Oyster propagation observations for 1913, J. Nelson (New Jersey Stas. Rpt. 1913, pp. 489-534, pls. 6).—These studies include the usual climatic data as to the amount of sunshine and rain, temperature, and winds, and observations on the temperature and saltness of the water, and the tidal ebb and flow, the progress of spawning by the oysters, the distribution and rate of growth of the embryo or larval oysters ("fry"), and the setting of the spat (E. S. R., 30, p. 374).

DAIRY FARMING-DAIRYING.

Report of dairy husbandman, A. S. Cook (New Jersey Stas. Rpt. 1913, pp. 293-333, 355-365, pls. 3).—Two lots of eight cows each, of practically uniform weight and production, were fed by the reversal system for two periods of 40 days each (10 days preliminary feeding intervening) on the following daily rations: Lot 1, an average of 3.42 lbs. of soy-bean meal; lot 2, 3.44 lbs. of cotton-seed meal, in addition to the regular basal ration of oats and pea hay, alfalfa hay, silage, green feed, beet pulp, and corn-and-cob meal, both lots receiving practically the same total amount of nutrients.

The production of milk was practically the same on each ration, there being a difference of only 275 lbs. in favor of cotton-seed meal in the entire period. The soy-bean ration produced 27.7 lbs. more of milk fat than the cotton-seed meal ration. The weights of cows during the experiment had the same uniformity as the milk produced, there being a difference of only 100 lbs. in favor of cotton-seed meal in the total weights of the two groups.

"The cost of milk was 2.2 cts, per quart on the cotton-seed meal ration and 2.3 cts, on the soy-bean meal ration. Results of this experiment indicate that when the price of cotton-seed meal is \$33 [per ton] the dairyman can afford to pay \$41 for soy-bean meal."

The average yearly milk yield for the 33 cows in the station herd was 8,547 lbs, per cow, the average milk fat yield 319.1 lbs; the average cost of roughage, figured at market price \$61.81, or when figured at the cost of production \$34.56; the average cost of grain \$51.54; the average profit with milk at 5 cts. per quart

\$91.80; the average returns per 100 lbs, expended for feed \$1.80; and the average cost of feed per quart of milk 2.8 cts.

Complete records are given of the feed consumed and cost of feed, together with the weight and average gain in weight per day for eight calves, for a period of six months. All of the calves were removed from the dam immediately after being dropped, and were fed whole milk during the first 30 or 40 days except two of the calves which were put on skim milk soon after birth. It was found that the average daily gain in weight was practically the same when the calves were fed skim milk as whole milk. The grain ration consisted largely of bran, gluten, and Ajax flakes. Grain was placed before each calf when they were about three weeks old and they were allowed to consume both grain and alfalfa at will.

It was found that when a small amount of oat meal and soaked beet pulp was added to the grain ration for the calves during the first few weeks they would consume more than when the straight grain mixture was fed. Another satisfactory mixture was found to be corn-and-cob meal, bran, and linseed meal, 8:4:1.

Data are given on the average daily rations, production, feed cost, and profit of cows of the various breeds as determined by records obtained in advanced registry work.

[Dairy husbandry], C. T. Ames (Mississippi Sta. Bul. 165 (1914), pp. 23-26).—At the Holly Springs substation the estimated cost of keeping a cow for 12 months was \$47.33, which included 150 days winter feeding at 15.5 cts. per day and 210 days of summer feeding at 4.8 cts. per day. It is stated that if the value of the manure is allowed to offset the cost of labor in running the dairy, each cow produced a net average of about \$65.16, which does not take into account the skim milk fed to pigs and calves nor the calves themselves.

Feeding the farm cow in the South (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 18, pp. 4).—General suggestions are given.

Advantages of dairying in the South (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 18, pp. 4).—A discussion of the advantages of dairying to the southern farmer.

Do you keep a cow? (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 16, pp. 4).—General information on dairying, designed for the cotton-belt farmers.

Milk records and cost of feeding cows in Berkshire, 1913, J. MACKINTOSH (Univ. Col. Reading, Dept. Agr. and Hort. Bul. 19 [1913], pp. 56).—Data are given, collected from 12 farms in Berkshire, England, on the cost of winter and summer feeding of dairy cows. A great variation was found among the several farms, and it is concluded that a material lowering of the cost of production could be effected if farmers would keep milk records and feed records and act on the information thus obtained.

[Milk production] (Mark Lane Express, 112 (1914), No. 4339, p. 589, fig. 1).— In connection with investigations carried out on a number of farms in Yorkshire, England, it was found that though high yield and low fat content and low yield and high fat content do not invariably go together, yet in the case of cows yielding under 400 gal. of milk, the milk contained an average percentage of 3.92 of fat. The percentage decreased with an increased milk production, and the milk of cows yielding over 1,000 gal, contained only 3.48 per cent fat.

The importance of milking at regular intervals was shown by the fact that of the 18 samples containing less than 3 per cent fat in the morning milk, no fewer than 13 were contributed by a farm where the intervals were very unequal. It was observed that while the lengthening of the night interval tends to raise the yield of milk and lower the percentage of fat in the morning milk-

ing as compared with the evening milking, it has little effect on the total weight of fat given at each milking.

On the law relating milk flow to age in dairy cattle, R. Pearl (*Proc. Soc. Expt. Biol. and Med., 12 (1914), No. 1, pp. 18, 19).*—The author finds that, contrary to the general assumption, the relation between the two variables milk flow and age is a strictly linear one. "The amount of milk produced by a cow in a given unit of time (7 days, 1 year, etc.) is a logarithmic function of the age of the cow." The law may be stated in the following way:

"Milk flow increases with increasing age but at a constantly diminishing rate (the increase in any given time being inversely proportional to the total amount of flow already attained) until a maximum flow is reached. After the age of maximum flow is passed the flow diminishes with advancing age and at an increasing rate. The rate of decrease after the maximum is, on the whole, much slower than the rate of increase preceding the maximum." In general the law applies to the absolute amount of fat produced in a given time as well as to the amount of milk.

General rules and regulations regarding the conduct of advanced registry tests in New Jersey, A. S. Cook (New Jersey Stas. Circ. 38, pp. 3-7).—This gives general directions to breeders and supervisors regarding the conduct of advanced registry tests in New Jersey.

The production and care of milk and cream (U. S. Dept. Agr., Office Sec. Spec. [Cire.], 1914, Dec. 31, pp. 4).—A popular discussion.

Handling milk in pint bottles, E. Kelly (Hoard's Dairyman, 48 (1915), No. 25, p. 745).—In surveys made by the U. S. Department of Agriculture of the relative number of milk bottles handled by milk dealers in five cities, it was found that a surprisingly large number of pint bottles are used. With 74 dealers an average of 1.39 pints was handled for each quart, and these constituted 41 per cent of the entire bottled milk. It is believed that because of the small profit made in some cases on milk handled in pints, it would be well for dealers to encourage the quart trade in every possible way.

The pasteurization of milk in the final package, B. W. Hammer and A. J. Hauser (Iowa Sta. Bul. 154 (1914), pp. 321-356, figs. 6).—In the work reported an effort was made to determine the most favorable vat temperature and time of exposure for final package pasteurization. The points considered in the determination were bacterial efficiency, creaming ability, and the heated flavor produced.

It was found that "the method of final package pasteurization must be regarded as a modified holding method because of the slowness with which the bottled milk can be heated or cooled.

"High pasteurization temperatures are unsatisfactory for the method of final package pasteurization because of the decreased creaming ability and pronounced heated flavor of milk so treated.

"An exposure of 50 minutes in water at 145° F. gave an average bacterial efficiency of 99.56 (13 experiments) and an average creaming ability of 94.68 (20 experiments). The heated flavor developed was so slight that only 8 persons out of 61 detected that the milk had been pasteurized.

"Milk pasteurized in the bottles with an exposure of 50 minutes in water at 145° was very satisfactory from the viewpoint of the consumer. Out of a total of 61 persons, 11 preferred the raw milk, 36 preferred the pasteurized, and 14 saw no difference.

"The intensity of the heated flavor in milk depended to a certain extent on the amount of fat present, inasmuch as the larger quantities of fat tended to mask the heated flavor. Because of the influence of various factors, such as the fat content, and also on account of the variations in the ability of different persons

to detect a heated flavor, it is believed to be impossible to make a statement with reference to the exposure necessary to produce this flavor.

"An exposure of 50 minutes at 145° is satisfactory for half pints, pints, or quarts of milk. Exposures satisfactory for milk appear to be satisfactory for cream, if we can judge from the results obtained with pint bottles.

"The exposure of milk to air during the heating process had no detectable influence on either the creaming ability or the detection of a heated flavor.

"Milk pasteurized in bottles by an exposure of 50 minutes in water at a temperature of 145° underwent much the same type of fermentation as good raw milk although in the former case the appearance of the fermentation was, as would be expected, materially delayed.

"As the vat temperature is increased above 145° the results obtained are progressively less desirable. A vat temperature of 140° is objectionable mainly on account of the long exposure necessary.

"With short exposures at various vat temperatures an increased creaming ability of the milk so treated was frequently observed but, with exposures which would satisfy the requirements regarding bacterial efficiency, such an increase was not observed.

"Final package pasteurization did not decrease undesirable flavors in milk and in some cases seemed to intensify them.

"Cream with a slightly increased acidity is undesirable for final package pasteurization because of the appearance of the heated cream as well as because of the sensation it gives to the tongue.

"A flavor was imparted to the milk by the paper lining of the cap in some cases. This defect has apparently been recognized by the manufacturers and a cap with a parchment paper lining is at present being made."

Experiments on the pasteurizing of milk in bottles, Weigmann (Mitt. Deut. Milchw. Vcr., 31 (1914), July, pp. 149-165, figs. 3).—Successful experiments are reported on pasteurizing milk in bottles at from 64 to 66° C. (147.2 to 150.8° F.) for ½ hour. The bacteria content was materially decreased and the keeping quality greatly increased. A variety of forms of bacteria were found in raw material but in the pasteurized product only lactic acid bacteria, isolated Bacillus mesentericus, and some few resistant forms were found. The apparatus and method of pasteurizing is described.

Testing and handling dairy products, C. Larsen and J. M. Fuller (South Dakota Sta. Bul. 152 (1914), pp. 28-56, figs. 8).—Items discussed in this bulletin are methods of testing milk and cream for milk fat, testing cream for acidity, care of the separator, causes of variation in the cream test, and methods of producing high quality cream.

Preserving milk samples for examination, J. Tillmans, A. Splittgerber, and H. Riffart (Ztschr. Untersuch. Nahr. u. Genussmtl., 27 (1914), No. 12, pp. 893-901).—In tests with various preservatives of milk it was found that thymol, phenol, creosote, and sodium fluorid cause the milk to coagulate after 24 to 48 hours. Bichromate of potash, owing to the intense yellow color it gives to milk, does not allow an accurate determination of the degree of acidity to be carried out. Chloroform causes an increase of refraction and of fat content, and creosote a decrease of specific gravity. Thymol and creosote weaken the diphenylamin reaction to a considerable extent, as is also the case with oil of mustard and phenol. Bichromate of potash causes the milk to give a strong positive reaction with diphenylamin, even without the addition of a nitrate.

Corrosive sublimate appears to be the most satisfactory of any of the preservatives tried. When used in a 0.04 to 0.03 per cent solution it preserves milk quite fresh for 120 hours without any noticeable increase in acidity. It has no action whatever upon the milk constants and allows the quantitative deter-

mination of nitrates to be carried out even after 120 hours. It is advised that Congo red at the rate of 0.2 cc. of 2 per cent solution be added to the sub-limate for every 250 cc. of milk. It has no effect upon the analysis of the milk and is a warning of the poisonous character of the preservative.

Water content of butter, W. Theorold (Ber. Nahrmil. Unitersuch. Amt. Bromberg., 1913, p. 16; abs. in Zischr. Unitersuch. Nahr. u. Genussmil., 28 (1914), No. 2, pp. 109, 110; Jour. Soc. Chem. Indus., 33 (1914), No. 22, p. 1106).—Tests indicate that butter does not increase in weight by absorption of water when moistened externally or placed in cold water for 70 hours. A sample of butter containing 22.9 per cent water showed 22.6 per cent after treatment, while another sample with 18.8 per cent showed 18.2 per cent.

Marketing butter and cream in the South (U. S. Dept. Agr., Office Sec. Spec. [Cire.], 1914, Dec. 19, pp. 3).—A brief discussion of methods.

Making farm butter in the South (U. S. Dept. Agr., Office See. Spec. [Circ.]. 1914, Dec. 28, pp. 4).—General suggestions are given.

Shall southern farmers build creameries? (U. S. Dept. Agr., Office Sec. Spec. [Cire.], 1914, Dec. 28, pp. 3).—A brief discussion on organizing and conducting a farmers' creamery.

Dairy bacteriology, A. Wolff (Molkereibakteriologische Betriebskontrolle. Berlin: P. Parcy, 1914, pp. VI+118, figs. 9).—This is a general text treating of the bacteriology of milk and its products, giving directions on methods of preparing cultures and identifying the various bacteria, and methods for the market control of dairy products.

Bacilli coli of milk, B. A. VAN KETEL (11. Cong. Internat. Pharm. [The Hague], 1913, Raps. 5. Sect., pp. 109-111).—It is stated that the usual source of contamination is the feces, the body of the cow, or the feed, and that the optimum temperature for growth is 37.5° C. (99.5° F.). There appeared to be a variety of opinions on the temperature required to destroy bacilli coli, ranging from 62 to 75°, and depending upon the duration of the period.

Analyses of the milk of sick cows, B. Sjollema (11. Cong. Internat. Pharm. [The Hague], 1913, Raps. 5. Sect., pp. 83-86).—It is stated that in general the milk of sick cows shows a greater degree of acidity and contains an increased quantity of the ferments catalase, reductase, and amylase. The lactose content is diminished, while the chlorin and albuminoids show an increase. In extreme cases the milk shows an abnormal color.

A study of streptococci isolated from certain presumably milk-borne epidemics of tonsilitis occurring in Massachusetts in 1913 and 1914, T. Smith and J. H. Brown (Jour. Med. Research, 31 (1915), No. 3, pp. 455-502).—After their extensive studies the authors conclude that the "streptococci causing epidemics of tonsilitis are not necessarily the same in different epidemics either in the same or different localities. . . . There is at present no satisfactory evidence that bovine streptococci associated with mastitis or garget are the agents of tonsilitis in man. Whenever cases of garget are suspected as sources of infection in man, both human and bovine types should be looked for."

Reindeer milk production, G. Grotenfelt (Malkeritid., 27 (1914), No. 22, pp. 399-411, figs. 24).—Analyses are given of reindeer milk, and methods of making reindeer cheese are described.

VETERINARY MEDICINE.

Annual reports of the official veterinarians of Prussia for 1910 and 1911, NEVERMANN (Veröffentl. Jahres-Vet. Ber. Tierärzte Preuss., 11 (1910 [pub. 1912]), pt. 1, pp. VI+136, pls. 17, flgs. 2; 11 (1910 [pub. 1913]), pt. 2, pp. IV+171; 12 (1911 [pub. 1913]), pts. 1, pp. VI+137, pls. 16; 2, pp. IV+131).—

These, the eleventh and twelfth annual reports (E. S. R., 27, p. 181), deal with the occurrence, etc., of animal diseases in Prussia. Much statistical data is presented in tabular form.

Veterinary calendar for the year 1915, edited by M. RAUTENBERG (Veterinär-Katender für das Jahr 1915. Berlin: August Hirschwald. 1914, 1. Abt., pp. XV1+308; 2. Abt., pp. VIII+585, figs. 65).—The forty-ninth annual edition of this publication. Part 1 includes directions for treating the more important diseases as prescribed in the Veterinary High School at Berlin; symptoms and therapy of poisoning, with chemical methods for detecting poisons; excerpts from materia medica; data on slaughter animals and meat inspection; the judgment of meat; veterinary jurisprudence; fees for veterinarians doing court work; and various tables (gestation, temperature, etc.) pertaining to veterinary matters.

Part 2 gives a list of the civil and military veterinary officials, and contains chapters on serodiagnosis, the microscopic examination of bacteria on cover glass preparations, the technique and significance of the urine examination, examination of feeds, and much data relating to the administration of laws germane to veterinary and public health practice. The fees set down by law for professional services are also included.

International catalogue of scientific literature. R—Bacteriology. QR—Serum physiology (Internat. Cat. Sci. Lit., 10 (1914), pp. VIII+602+182+23).—This deals with some of the literature of bacteriology and serology. Topics coming under the latter heading are now grouped in a separate chapter entitled Serum Physiology. The American literature is not treated adequately.

Animal castration, G. R. White (Nashville, Tenn.: Author, 1914, pp. 241, figs. 209).—A well-illustrated work dealing with the subject as it relates to the equine, bovine, porcine, ovine, canine, feline, and fowl. The deodorization of the skunk is also considered.

Special veterinary therapy, M. R. Steffen (Chicago: Amer. Jour. Vet. Med., 1914, pp. 97).—A collection of therapeutic notes based upon more than ten years' active practice by the author.

The use of drugs in the treatment of disease caused by nematode worms, J. F. Craig (Amer. Vet. Rev., 46 (1915), No. 5, pp. 490-509).—A somewhat detailed discussion of this subject, which was presented at the Tenth International Veterinary Congress held at London in 1914.

Animal immunity, W. ROSENTHAL (Tierische. Immunität. Brunswick: F. Vieweg & Son, 1914, pp. X+329, fig. 1).—This work is intended for the non-technical man, the student of medicine, and the physician not yet versed in the science of immunity.

The vitamins, C. Funk (Die Vitamine. Wiesbaden: J. F. Bergmann, 1914, pp. VIII+193, pls. 2, figs. 38).—This deals with the significance which the vitamins have for physiology and pathology, with special reference to the avitaminoses (beri-beri, scorbutus, pellagra, and rickets). An appendix is included which deals with the growth substances and the cancer problem.

A chapter bearing on the possible relation of the vitamins to "stijfziekte" and "lamziekte" (Theiler) in horses is also included. Discussing the subject the author points out that investigations are necessary to prove this relation.

Experimental study of the Abderhalden test, A. H. Bunce (Abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 19, p. 1499).—Out of 34 tests for pregnancy 16 were positive and 17 negative. In no case was a negative reaction obtained in a proved pregnancy. In the preliminary work contradictory results were obtained, but this was due to faulty technique, such as taking serum from patients soon after meals, when the blood was charged with much amino acid.

The method may also serve as a valuable aid for subtantiating and strengthening clinical results in doubtful cases.

About a new skin reaction for diagnosing pregnancy, E. Engelhorn and H. Wintz (München, Med. Wehnschr., 61 (1914), No. 13, pp. 689, 690, flg. 1; abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 19, p. 1514).—The reaction is conducted in a manner similar to the tuberculin and luctin reactions, viz, by injecting the alien protein into the skin. In the test an extract of the placenta, termed "placentin," was used.

"In 70 pregnant women a reaction in the skin was constantly obtained, while there was no reaction in 53 men and children and nonpregnant women. The only contradictory finding was a positive reaction in one child of six with bladder disease. The reaction became positive in pregnant women from the seventh week on and persisted for three or four days after delivery."

On the filterability and biology of spirochetes, S. B. Wolbach (Amer. Jour. Trop. Diseases and Prev. Med., 2 (1915), No. 8, pp. 494-505, pls. 2).—The author's conclusions are "that the method of filtration as a means of separating spiral organisms from ordinary bacteria will probably hold good for other saprophytic and pathogenic spirochetes and allied micro-organisms; that organisms larger than many bacteria will pass the Berkefeld V, N, and W filters, namely, Spirocheta duttoni, and the ones we have tentatively called S. elusa, S. biflexa, and the spiral organism from the colon of man, which is probably the organism commonly recognized in preparation as an 'intestinal spirochete'; that there is no evidence of spirochetes multiplying by any other method than single fission. It is certain that the granules, coiled forms, and swollen terminals of the spiral organisms cultivated by us are not capable of multiplication in any form."

A simple method for the preparation of stable control extracts for anthrax precipitation, B. Schubert (Berlin, Tierärztl, Wehnschr., 30 (1914), No. 9, pp. 151, 152).—In the directions given for conducting the Ascoli procedure the making of two control tests is recommended for the purpose of excluding the possibility of errors, but the precipitation each time of a control extract is not convenient. By preparing ½ cc. of the extract in the regular manner, filtering through asbestos into test tubes, and sterilizing for ten minutes for three successive days, a stable extract which may be used at any time is obtained. If a precipitation occurs after the first sterilization, the solution in the tubes is filtered through asbestos again in the manner described.

Nerve degeneration in fowls fed on unhusked rice (palay), R. B. Gibson and I. Concepcion (Philippine Jour. Sci., Sect. B, 9 (1914), No. 1, pp. 119-123, pl. 1).—From this work it appears that the substitution of rough rice for the polished article is not completely protective against beri-beri in all individuals. The authors state that "we do not mean to say that this substitution has not practically eliminated beri-beri where it has been undertaken or that the use of rice polishing is not without great therapeutic value. But in view of the accumulated evidence, we can say that the addition of other feedstuffs to a diet of unpolished rice is essential to meet the normal nutritive requirements of the body."

[Foot-and-mouth disease] (Cornell Vet., 4 (1915), No. 5, pp. 221–259, pls. 8, flgs. 3).—A number of articles are here presented which relate to foot-and-mouth disease, namely, The Outbreak of Foot-and-Mouth Disease, by P. A. Fish (pp. 221–223); History of Foot-and-Mouth Disease, by J. Law (pp. 224–230); The Nature of Foot-and-Mouth Disease (pp. 231–234), Economic Significance and Methods for Control (pp. 247–250), and What Animal Owners Should Do to Prevent Foot-and-Mouth Disease (pp. 256–258), by V. A. Moore; Etiology and Morbid Anatomy, by C. P. Fitch (pp. 235–239); Symptomatology, by R. R. Birch (pp. 240, 241); Diagnosis and Differential Diagnosis, by D. H. Udall

(pp. 242-246); and Foot-and-Mouth Disease in New York State, 1914, by J. G. Wills (pp. 251-255).

The foot-and-mouth disease, what it is, what it does, how to fight it, and how to prevent it (Garden City, N. V.: Doubleday, Page & Co., 1914, pp. 19, figs. 6).—This pamphlet embraces several articles, namely, Every Farmer's Duty in the Present Foot-and-Mouth Crisis, by V. A. Moore (pp. 3-7); Foot-and-Mouth Disease, Its Nature, Symptoms, Effects, and Treatment (pp. 8-16); and Historical Notes and Data Concerning the Disease in This Country and Abroad (pp. 17-19).

Foot-and-mouth disease [in the United States] (Amer. Vet. Rev., 46 (1915), No. 4, pp. 380-397).—This is a discussion of the outbreaks of foot-and-mouth disease that have occurred in this country.

About the utilization of the conglutination reaction as a diagnostic test for glanders, C. W. Andersen (Centbl. Bakt. [etc.], 1. Abt., Orig., 72 (1913), No. 4-5, pp. 394-398; abs. in Berlin. Tierärztl. Wehnschr., 30 (1914), No. 7, p. 124).—The conglutination reaction (E. S. R., 28, p. 478) was studied with the sera from 225 horses. Parallel tests were run with the complement fixation method.

Fourteen of the sera reacted positively, and in 13 of the horses on section glanderous lesions were noted. In the fourteenth horse some old nodules were found in the lung. The complement fixation and the mallein tests showed positive in the latter case. Four sera gave partial fixation in the complement binding test but negative findings with the conglutination test. The four horses were found sound on autopsy. Two hundred and one sera gave negative complement fixation and conglutination reactions. The author believes the conglutination test is more sensitive and specific for diagnosing glanders than the complement fixation test. This work supports the findings of Stranigg.

The ophthalmic test in the diagnosis of glanders, F. Favero (Mod. Zooiatro, Parte Sci., 25 (1914), No. 2, pp. 49-63; abs. in Jour. Compar. Path. and Ther., 27 (1914), No. 3, pp. 267-269).—"The ophthalmic test does not always clearly indicate the existence of glanders. A positive ophthalmic test is specific. It is essentially a muco-purulent secretion which persists for at least 24 hours. In doubtful cases the ophthalmic test repeated at a short interval gives confirmatory results. In a positive reaction there is a high percentage of neutrophile polynuclear leucocytes in the conjunctival exudate, but this character is not specific."

An ophthalmic mallein eye dropper, W. Wilson (Amer. Vet. Rev., 46 (1914), No. 1, p. 62, figs. 3).—The apparatus consists of an ordinary medicine dropper with the point drawn out and bent at right angles. The tip of the dropper is fitted into a notch made in a camel's-hair brush just next to the hair, and the dropper is fastened by means of a clamp made from a thin piece of sheet copper. "By filling the dropper with mallein, which easily holds 10 to 20 doses, it may be squeezed out into the brush and placed into the eye, and any remaining in the dropper after the testing is completed may be returned to the bottle without being badly contaminated."

Simultaneous method of inoculating cattle and carabaos with serum from animals that have been recently immunized, A. R. Ward and F. W. Wood (Philippine Jour. Sci., Sect. B. 9 (1914), No. 1, pp. 125–135, pls. 3).—Experiences with the simultaneous inoculation method utilizing blood drawn in the field have demonstrated "that there is no necessity for maintaining an expensive permanent laboratory and herd for the production of artirinderpest serum from hyperimmunized animals. A radical reduction in the cost of serum production has been effected, and in consequence the possibility of extensive employment of simultaneous inoculation in combating rinderpest has been demonstrated."

A note on surra in camels, H. E. Cross (Lahore, India: Gort., 1914, pp. 8).— A brief account with directions for the diagnosis of the disease through a study of the blood, symptoms, and post-mortem appearances; the treatment, etc.

Wholesale handling of bovine tuberculosis in Colorado, W. W. Yard (Amer. Vet. Rev., 46 (1914), No. 1, pp. 56-59).—A statement about the occurrence of tuberculosis amongst bovines and pigs on a farm owned by one of the richest men in Colorado, and illustrating some of the difficulties which may be encountered by an official veterinarian in eradicating tuberculosis from a herd in which the support of the owner is not given. Stock worth \$75,000 was destroyed.

The diseases of the internal generative organs in relation to dairy inspection, W. L. Williams (*Rpt. N. Y. State Vet. Col., 1912–13, pp. 193–200*).—This is a general discussion of the diseases of the internal generative organs that are of importance in dairy inspection.

A study of infectious abortion in cattle, V. A. Moore and C. P. Fitch (*Rpt. N. Y. State Vet. Col., 1912–13. pp. 82–114*).—This article discusses the cause, channels of infection, experimental infection, elimination of the causative organism, diagnosis, treatment, immunity, and control. A more recent report on this disease by Williams has been noted (E. S. R., 31, p. 779).

A bibliography of 67 titles is appended.

Experiments on the control of warble flies in Germany, Schöttler and Gläser (Mitt. Ausschusses Bekämpf. Dasselplage, No. 6 (1914), pp. 1-31; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 9, pp. 1189, 1190).—This report of the work of the Warble Control Committee carried on during 1913 in the district of Neuhaus on the Oste is in continuation of that previously noted (E. S. R., 32, p. 60). Of the 3,892 head of cattle treated, 75.4 per cent were freed from warbles, an average of 16.2 larvæ per head being removed.

In a second part of the paper a campaign against warbles in a district in the grand duchy of Oldenburg is reported upon. An experiment in which ten steers were kept under exactly the same conditions, five being freed from warbles and the others not, indicated that the loss in flesh caused by warbles amounts to more than the loss caused through damage to the hides.

The effect of the cattle tick upon the milk production of dairy cows. T. E. WOODWARD, W. F. TURNER, and C. CURTICE (U. S. Dept. Agr. Bul. 147 (1915), pp. 22, figs. 6).—This bulletin reports upon an experiment undertaken with a view to definitely determining the direct effect of the cattle tick (Margaropus annulatus) on the milk production and body weight of dairy cows.

In conducting the experiment, twenty grade Jersey cows of average dairy quality and in fair condition of flesh, all being immune to ordinary attacks of tick fever, were selected in the early part of their lactation periods. They were divided into two groups of ten animals each, one being freed from ticks and kept free, the other being kept tick-infested by applying seed ticks at regular intervals. The experiment began May 21, 1913, and lasted during a period of 140 days. The milk of each cow was weighed and a sample taken at every milking for a composite fat test at the end of each ten-day period. The body weights were taken for ten consecutive days at the beginning of the work; thence once every ten days until the last period, when they were taken for ten consecutive days as at the beginning of the work.

The investigations show that the eattle tick has a decidedly injurious effect upon supposedly immune dairy cattle, the extent of the injury being largely dependent upon the degree of infestation. The effect is more pronounced upon the milk production than upon the body weights when a sufficient supply of food is given.

"At the beginning of the test the tick-free and tick-infested groups gave practically the same amounts of milk; at the close the tick-infested gave only 65.8 per cent as much as the tick-free. The tick-free group gained 6.1 per cent in body weight; the tick-infested 3.6 per cent.

"Spraying or dipping tick-free cattle in an arsenical solution causes a marked though temporary decrease in milk flow. In this experiment there was an average reduction of 6.1 per cent from the normal milk flow for a period of five days following each of the four applications of the arsenical solution.

"Resistance of cattle to infestation by the tick is a variable quality. Of the ten animals in the tick-infested group, four became grossly infested; two more so than the average, and the remaining four but lightly infested.

"The death of cow 15, due to excessive tick infestation, and various recurrences of fever in the other animals, emphasizes the extreme hazard of cattle being continuously subjected to these losses by the tick. Cow 15 was one of the best of the tick-infested group and represented at least a 10 per cent loss from the capital invested in tick-infested cows. Furthermore, the losses observed in this experiment were sustained on rations sufficient to maintain body weights. It is thought that had there been but a scant supply of food, as sometimes occurs when cows are on pasture, the tick-infested cattle would have suffered earlier and probably to a greater degree than they did. The losses in this case were in spite of a good maintenance ration. It is probable that much of the spring losses in cattle now laid to starvation, due to lack of pasturage, is materially aided by blood depletion due to ticks, and that repeated dippings would save many cattle otherwise lost.

"These experiments are not extensive enought to furnish an exact measure of the amount of decrease in milk flow due to infestation, but they show that the losses are considerable and vary in immune cows largely in proportion to the extent of infestation, since in all cases the milk flow decreased faster in the heavily infested than in the lightly infested cows. This is additional evidence that the tick is a great hindrance to profitable dairying in the South. Even in so-called immune cattle, ticks cause irritation of the skin and withdraw blood that otherwise would produce milk or meat."

The dairy records of the experimental cows are given in tabular form in an appendix.

Investigations in regard to the action of immune sera against calf dysentery (scours) in infections with the bacteria of the coli and aerogenes group, O. Stenström (Svensk Vet. Tidskr., 18 (1913), No. 3, pp. 73-83; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 59 (1913), No. 7, p. 216).—This is a study of the C. O. Jensen anticoli serum. The serum was able to fix complement. saturated with antigen and then centrifuged for the purpose of removing the antigen the immunizing powers of the serum for guinea pigs were only slightly reduced. Bacteria killed with toluol and suspended in sterile distilled water were fatal for guinea pigs (endotoxic action). The toxic action was prevented by immune serum but not according to the law of multiples. The serum therefore apparently contains antitoxins, but its action is not entirely antitoxic. Leucocytes from exudates also acted antitoxic. In dilute solutions the serum predisposes toward phagocytic action. Antiaggressins were detected in the animal experiments, and the chief value of the serum is dependent upon the presence of these substances.

Studies on the hematology of normal and cholera infected hogs, R. R. DINWIDDIE (Arkansas Sta. Bul. 120 (1914), pp. 21-41, figs. 8).—In the course of a somewhat prolonged study of the blood of normal pigs and that of pigs

infected with hog cholera some peculiaritles in the red blood corpuscles were observed.

When red blood corpuscles were studied in a fresh (unfixed and unstained) state they were found to throw out, from their margins, processes from the cytoplasm as active bodies of various bizarre forms which, in part, form the plasma granules seen by dark ground illumination. A more common feature of pigs' blood, and one which distinguishes it from any other animal species, is the occurrence within the area of the red cell of refringent motile bodies, which, with the highest of magnifications, show a certain degree of uniformlty in shape and are apparently intracellular. They usually lie near the margin of the cell, but in their migrations they may alternately be above or below the focus, but never beyond the margin of the cell. Although first observed in normal pigs, they were noted in much increased quantities in the blood of hogs affected with cholera. The motility is inhibited by cold but goes on at ordinary room temperature, i. e., 70° or upward. "The motility of these endoglobular bodies is not to be compared with that of bacteria, nor can it be properly described as ameboid, nor yet as molecular."

"Omitting the smallest bodies too minute to allow recognition of their shape these bodies occur in three distinct forms: (1) As round or short oval slightly biconcave flattened disks; (2) as long oval or rice grain-like bodies; (3) as crescentic or horseshoc-like forms. All of these forms may be found in the same blood sample. Usually the disk form is most abundant. It also exhibits the most active motility and the greatest diversity in size." The crescentic or horseshoe shaped forms are the most sluggish in motion.

"The erythrocytes in which these bodies occur may be of normal size or slightly larger or smaller than the average and are not commonly otherwise distorted. Most frequently they occur singly in the cell, but doubles are nearly as common and six or eight may be found. Those cells which carry such numbers are generally smaller than the average, and I have only found them in cholera-infected blood." The cells in which these motile bodies are present are not obviously deficient in hemoglobin.

"Between the cells in pigs' blood and more numerously in infected blood, a variety of minute quivering or dancing bodies may be seen, the origin and nature of which I do not know." These may be offshoots of erythrocytes and are increased some hours after collecting the blood.

"In diseased blood (cholera infected) the intercellular or plasma granules are usually more numerous than in normal blood. In all pigs' blood they are greatly more numerous than in the blood of man." Spirochetes as observed by King (E. S. R., 30, p. 383) were not found.

In stained specimens of pigs' blood small round solidly stained bodies were seen within the erythrocytes. Only one of these coccoid bodies is usually present and it is eccentrically placed in the blood cell. "With methylene blue or Jenner's stain they are colored blue, with Giemsa, a dark ruby red. As to the crythrocytes, in which they occur, they are, with the exception to be noted, not otherwise abnormal. In the blood of some infected animals in which marked anisocytosis was present with diminished red cell count, most of these bodies would be found within enlarged cells (megalocytes) with deficient hemoglobin. In the same preparation, however, bodies would be seen within microcytes or cells of normal size. Unusual numbers of these bodies in any specimen were found quite generally associated with such abnormalities in the erythrocytes. Erythroblasts may be found in preparations from the blood of normal or noninfected pigs. They are often more abundant in the blood of cholera-infected animals, especially at a late stage of a chronic form of the

disease, but are never sufficiently abundant to form a feature of cholera infection."

Although intracellular bodies are increased as a rule quite markedly by an infection, this is not invariably the case. They are in some way connected, according to the author, or associated at least with conditions which give rise to malnutrition and anemia, and when a marked increase in number takes place, there is a corresponding decrease in the number of red cells.

The blood of three suckling pigs, four or five weeks old and farrowed by a mother which had been immunized for antiserum production, showed anemia, especially the fattest of the three, although all of the animals were apparently healthy in appearance. In all three the intracorpuscular bodies were unusually abundant. The bodies in pigs' blood are regarded as identical with the Jolly bodies of other workers and bear a close relation to the figures of Theiler's anaplasma, the reputed cause of gall sickness of South African cattle. Attempts to transfer these bodies to the guinea pig were unsuccessful.

In a small percentage of cases of acute hog cholera blood films treated with Giemsa or Wright stain showed the presence of ring-shaped forms. These had the appearance of being plastered over the surface of the red cells, some projecting beyond the margins, and even lying intercellular. "The rings are colored by the nuclear staining component of the stain various shades of purple to red. As already said, these ring forms are apparently absent or so rare as to escape observation in most samples of cholera blood, but in some cases they are exceedingly numerous. They appear in all preparations made from the same blood sample and are absent from others similarly treated for comparison, hence are attributable to the condition of the blood and not to defect in staining." Although these forms have never been noted in the blood of noninfected animals, they have not been sufficiently studied to allow of the suggestion that they are characteristic of cholera. They bear no resemblance to bacteria in either staining, properties, or shape. According to the author's present opinion they are foreign organisms of some kind, if not bacterial probably protozoal.

"Hog-cholera infection gives rise at an early stage to a pronounced leucopenia, with the appearance of numerous atypical mononuclear or transitional leucocytes. When inflammatory complications occur a polymorph leucocytosis appears. The destruction of red corpuscles is not a prominent feature of the disease."

[Hog cholera in New Jersey], F. C. MINKLER (New Jersey Stas. Circ. 40 (1914), pp. 21-29; Rpt. 1913, pp. 199-207).—The author describes the nature of hog cholera and preventive and remedial measures. A number of outbreaks were encountered in the State during 1913.

Atlas of equine anatomy, R. Schmaltz (Atlas de Anatomie des Pferdes, Berlin: Richard Schoetz, 1914, pt. 3, pp. 20, pls. 14).—This third part of the work previously noted (E. S. R., 24, p. 485) deals with the position of the viscera as based upon studies of frozen subjects. Colored illustrations of twelve cross sections made of the trunk show the organs in situ.

The common colics of the horse, their causes, symptoms, diagnosis, and treatment, H. C. Reeks (*Chicago: Alexander Eger, 1914, 3. ed., pp. XVI+369, figs. 32*).—An enlarged edition of the work previously noted (E. S. R., 14, p. 922).

Dourine in Nebraska, L. C. Kigin (Amer. Vet. Rev., 46 (1915), No. 5, pp. 563, 564).—This article records the discovery of the occurrence of dourine in Nebraska during the fall of 1914. It is thought to have entered the State in a shipment of horses from Wyoming.

[Poultry diseases], H. R. Lewis and A. L. Clark (New Jersey Stas. Rpt. 1913, pp. 276-279).—The authors report upon an outbreak of vent gleet among

recently purchased Buff Orpingtons at the poultry plant on the college farm, as a result of which the average egg production for the year was but 25 per cent of the theoretical. The percentage of fertility of the eggs was low, about 60, although apparently good vigorous male birds were used. The disease was found to be very hard to overcome and it is concluded that in dealing with it the best method lies in the destruction of the affected fowis.

In an attack of roup that broke out at the plant in January about the only birds affected were those in the pens laying the heaviest. Control measures consisted in the isolation of affected fowls as soon as detected. Most of the affected birds were treated and recovery resulted in a week or ten days.

The necessity of meat inspection of poultry, with especial regard to tuberculosis, A. Breuer (Hússzemle, 8 (1913), No. 11, pp. 81-83; abs. in Berlin. Tierärztl. Wehnschr., 30 (1914), No. 12, p. 206).—The importance of examining the viscera of poultry, in addition to other parts, is pointed out. Where this is not done great danger exists of spreading the disease. At the Budapest abattoir 8,337 head of poultry shipped from Servia were examined, and of this number 188 were tubercular, of which 183 were diseased only in a few organs, especially in the digestive tract. In the Budapest market tuberculosis in fowls is said to be present to the extent of from 6 to 13 per cent.

RURAL ENGINEERING.

Wood pipe for conveying water for irrigation, S. O. Jayne (U. S. Dept. Agr. Bul. 155 (1914), pp. 40, pls. 4, figs. 7).—This bulletin deals with the design, construction, durability, possibilities, and limitations of continuous and machine-banded wood pipe for several classes of service and is intended to be of interest to irrigation engineers, owners of irrigation works, water power companies, and water departments of municipalities. The studies reported included the inspection of many pipe lines throughout several western States, interviews and correspondence with manufacturers, builders, and operators of wood pipe, and a review of published data on the subject.

As regards the durability of wood pipe, data are presented to show that the length of time any pipe will last can not be accurately predicted without a thorough knowledge of all the conditions involved. "With pipes buried in the ground the wood will endure longest where the air is most nearly excluded either by a high internal pressure which completely saturates it or by a deep covering of very fine soil... In contact with the soil wood pipe decays more rapidly under a light head than it does under heavy pressure, and other things being equal, it usually decays more rapidly in a porous open soil, such as sand or gravel, than it does in a fine soil of silt or clay, because the finer soil is more effective in excluding the air. Experience appears to indicate also that wood decays more rapidly in a loamy soil, rich in humus or partially decayed organic matter, than it does in one containing little or none....

"The life of exposed pipes may be prolonged by promptly stopping all leaks as they develop and by keeping the exterior dry. The decay of buried pipes has also in some instances been arrested by removing the covering and leaving them exposed. . . . Where pipes are to be placed in contact with the soil, and where the internal pressure is not sufficient to insure complete saturation of the staves, it is probable that their durability may be increased by treating with some preservative. . . .

"Contrary to the theories commonly held thirty years ago, it has been found that the durability of wood pipe is usually dependent on the life of the wood rather than on the life of the bands. . . . Corrosion of the bands . . . usually occurs most rapidly where pipes are buried and the backfill is wet, under con-

ditions which, as a rule, are most favorable for the life of the wood. Corrosion is greatly accelerated by the presence of alkali in the soil.... Under such conditions the bands almost invariably fail at the bottom of the pipe....

"With so many influences affecting the life of wood pipe no attempt should be made to strike an average of durability except in cases where attending conditions are known to be the same. Where pipes are fully exposed and supported free from all contact with the soil the conditions are much less variable than otherwise, and a life of at least twenty years may be quite reasonably expected for either fir or redwood if properly maintained. If placed in the ground or in contact with the soil, the life of wood pipe may, under very favorable conditions, be much greater than twenty years, otherwise it may be a great deal less. In contact with soil the durability is nearly always a matter of some uncertainty."

Irrigation investigations, G. E. P. Smith and A. L. Enger (Arizona Sta. Rpt., 1913, pp. 280-285).—Further experiments with reinforced concrete caisson curbs (E. S. R., 29, p. 484) demonstrated their effectiveness for developing shallow wells.

Measurements of the surface flow of Sabino Canyon in the vicinity of Tucson from 1904 to 1912 indicate that the available supply is sufficiently large, but that "the remarkable disparity between the discharges of such years as 1904 and 1910 and those of 1905 and 1907, together with the fact that there is a tendency for several lean years to come together, necessitates much greater storage capacity for a reservoir project than would be the case if the rainfall, and hence the run-off, were more evenly distributed."

Experiments as to the necessary slope of the land in border irigation indicated that "under ordinary conditions it is best to run the borders down the steepest slope, or nearly so, and thus reduce the cost of grading the land to a minimum, and then to adjust the width and length of the lands to the head of water. The effects of silts in river irrigating waters must be considered, inasmuch as these silts tend to settle out at the head ends of the lands, making those ends more impervious to water than the lower ends. These deposits, also, produce a slope lengthwise of the land. The tightening effect of the silt blanket must be counteracted so far as possible by the various methods of cultivation in use. The amount of desirable slope is influenced further by the kind of crop, alfalfa requiring more than crops which are irrigated between rows. But with clear or moderately clear water lands should never be graded entirely level."

Relations between physical constitution of soils and the distribution of irrigation waters, A. MÜNTZ and E. LAINÉ (Min. Agr. [France], Ann. Foréts, Hydraul. [etc.], No. 44 (1912), pp. 1-130, pls. 7, figs. 9).—In continuation of previous studies on the relation of the physical properties of the soil to irrigation (E. S. R., 24, p. 522) the authors extended their investigations to include the module, and time, method, and amount of irrigation most favorable to crops, with particular reference to the design of irrigation works.

The permeability of the soils used in the experiments varied from an infiltration of 0.5 to 60 cm. (0.2 to 23.4 in.) per hour. In the module experiments it was found that for the less permeable soils the module should be such that the flow through the diversion gate is about 0.3 liters per second per meter of width of the irrigated parcel. For soils of average permeability this should be from 1½ to 2 liters per second and for extremely permeable soils should exceed 9 liters per second per meter of width of the irrigated parcel. It is also concluded in this connection that the improper choice of module is one of the main causes of failure in irrigation.

Irrigation experiments with hay crops showed that the most economical amount for an irrigation is an amount just sufficient to reach the extremities

of an irrigated plat, which amount should be predetermined for each plat on the basis of the physical properties of its soils. A greater amount than this is concluded to be a waste of water and more or less of an injury to the soil.

On the soils of varying permeabilities irrigation was found to be on the average most effective and practical when applied in predetermined amounts at intervals of seven or eight days. Very inferior results were obtained when irrigation water was applied at intervals of 15 days and of three weeks. It was further found that on these soils the necessary total quantity of water for crops computed on the basis of continual flow during the growing season varied from 0.23 to 0.85 liters per second per hectare according to the physical properties of the soil. The commonly assumed need for all soils of a continual flow of 1 liter per second per hectare is thought to be a great waste of water.

Irrigation, R. T. Burdick (Vermont Sta. Bul. 182 (1914), pp. 340-363, pls. 4).—The author discusses the general topic of irrigation and states that vegetables, small fruits, and potatoes can be best irrigated in Vermont. He briefly describes various methods of applying water, including subirrigation and sprinkling. It is considered unsafe to apply more than 1 in. of water to crops at a time, owing to the uncertainty regarding rainfall. Brief descriptions of several irrigation plants in operation in the Eastern States are given and a list of references to related literature is appended.

Surface water supply of North Pacific coast drainage basins, 1911, F. F. Henshaw et al. (U. S. Geol. Survey, Water-Supply Paper 312 (1915), pp. 706, pls. 4).—This report presents the results of measurements of flow made on the streams in the North Pacific coast drainage basin and their tributaries during 1911.

Surface water supply of the Great Basin, 1912, F. F. HENSHAW, E. A. PORTER, and G. C. STEVENS (U. S. Geol. Survey, Water-Supply Paper 330 (1914), pp. 275, pls. 3).—This report, prepared in cooperation with the States of Idaho, Utah. Oregon, California, and Nevada, presents the results of measurements of flow made in the Great Salt Lake, Sevier Lake. Thousand Springs Creek, Salton Sink, Owens Lake, Mono Lake, Walker Lake. Humboldt-Carson Sink. Pyramid Lake, Winnemucca Lake, Warner Lake, Albert Lake, Silver Lake, Mauheur Lake, Harney Lake, and Alvord Lake drainage basins during 1912.

Surface water supply of lower Columbia River and Rogue, Umpqua, and Siletz rivers, 1912, F. F. Henshaw and E. S. Fuller (U. S. Geol. Survey, Water-Supply Paper 332-C (1914), pp. 226).—This report, prepared in cooperation with the States of Oregon and Washington, presents measurements of flow made on the lower Columbia River and the Rogue, Umpqua, and Siletz rivers during 1912.

Surface water supply of the Pacific coast in California, 1912, H. D. McGlashan and G. C. Stevens (U. S. Geol. Survey, Water-Supply Paper 331 (1914), pp. 442, pls. 2).—This report presents the results of measurements of flow made on streams in the northern and southern Pacific Ocean drainage basins and in the San Francisco Bay drainage basin during 1912. An article on Fluctuations in Ground-water Levels in the Valley of Southern California, by W. C. Mendenhall, is included.

Springs of California, G. A. Waring (U. S. Geol. Survey, Water-Supply Paper 338 (1915), pp. 410, pls. 13. figs. 4).—This is a popular catalogue of the spring waters of California, referring particularly to their chemical properties, and including analyses.

Profile surveys in Bear River basin, Idaho (U. S. Geol. Survey, Water-Supply Paper 350 (1914), pp. 7, pls. 6).—This report, prepared under the direc-

tion of R. B. Marshall, describes the general features of the Bear River basin and gives a plan and profile of the river from Riverdale to Novene, Idaho.

Profile surveys of Snoqualmie, Sultan, and Skykomish rivers. Washington & U. S. Gool. Survey, Water-Supply Paper 366 (1914), pp. 7, pls. 12).—In this paper, prepared under the direction of R. B. Marshall, the general features of the Snohomish River basin are described and plan and profile maps of the Snoqualmie, Sultan, and Skykomish rivers and certain of their tributaries are given.

Profile surveys of Missouri River from Great Falls to Three Forks, Montana (U. S. Geol. Survey, Water-Supply Paper 367 (1914), pp. 8, pls. 13).—This report, prepared under the direction of R. B. Marshall, describes the general features of the Missouri River basin and gives a plan and profile of the river from Great Falls to Three Forks, Montana.

The diaphragm method of measuring the flow of water in open channels of uniform cross section (*Engin. and Contract.*, 42 (1914), No. 18, pp. 414, 415, figs. 4).—The diaphragm method is described and two examples of apparatus are illustrated.

German experiments with one apparatus using calibrated orifices to check the diaphragm method showed a close agreement and that the diaphragm gave accurate measurements with velocities as low as 0.02 ft. per second. Another test, using the current meter as a check, showed that the diaphragm gagings checked the meter gagings very closely, the greatest difference obtained by a direct comparison being 0.7 per cent.

The chief advantage of the diaphragm method is said to be the rapidity with which the measurement can be made. The disadvantages are that a channel of sufficient length and uniform section must be available and that the cost of installing the necessary apparatus is rather high.

List of references on water rights and the control of waters (Washington: Library of Congress, 1914, pp. 111).—It is the purpose of this list to bring together the more important discussions of the various claims put forth by conflicting interests, including irrigation and power development concerns and properties largely dependent for their value upon the continuance of natural stream flow, and to point out by means of an analytical index where information on any phase of the subject may be found.

Draining District 9, Mississippi County, Arkansas, L. L. Hidder (Engin. Rec., 70 (1914), No. 17, pp. 455-457, figs. 2).—The methods of design and execution of the work for an improvement involving 14.000,000 cu yds. of dredged excavation to prevent river overflow and provide local drainage benefiting 300 square miles of land are presented.

The main features of the district plans are (1) protection from overflow from the Little River, (2) a system of lateral drainage through the entire territory, and (3) a system of outlet channels to carry to a final outlet the water collected in the lateral drains. A survey of the existing information regarding the run-off

of the district led to the development of the formula $R = \frac{28}{\sqrt{M}} + 7.2$, in which R

equals run-off in second-feet and M equals the area in square miles. The so-called fish-bone system of drainage was rejected owing to the fact that too large and unwieldly a channel would be necessary and would make the effective distribution of slope difficult. In its stead a 4-channel plan was adopted.

The estimated cost of the excavation was \$1.155.000.

Comparative steam and electric power layouts for a drainage pumping plant (Engin. and Contract., 42 (1914), No. 18, pp. 412-414, figs. 5).—Comparative plans and bidding prices for the two types of pumping plant are given with

descriptions of the essential structural features. The steam pumping plant bid was awarded the contract.

Building levees with the hydraulic dredge, J. M. ALLEN (Engin. News, 72 (1914), No. 18, pp. 891-893, figs. 3).—A description of the plant and methods used in building levees with hydraulic dredges on different rivers is given with cost data of the operation of a typical plant. See also a previous note by Yarnell (E. S. R., 32, p. 187).

Some methods and costs of cleaning drainage ditches, S. Dean (Engin. and Contract., 42 (1914), No. 18, pp. 415, 416).—A hydraulic jib outiit for removing silt from a drainage canal is described and cost data are given. Cost data are also given for the use of a small drag line excavator for the same purpose.

Country roads in southeastern Wisconsin (Engin. Rec., 70 (1914), No. 17, pp. 448-450, figs. 5).—This article deals with state aid road construction, including innovations in the way of clay-bound macadam, high earth shoulders on narrow roads, and increased thickness of concrete of a richer mixture.

Blasting cultivation on moor soil, W. Bersch (Ztschr. Moorkultur u. Torfverwert., 12 (1914), No. 4, pp. 140-146, figs. 5).—In a review of various blasting experiments it is stated that soil breaking and drainage ditch digging in moor soil by means of explosives are unsuccessful owing to the fact that the circumference and depth of activity are too great and can not be so well controlled as in mineral soils.

Use of logging equipment for clearing land of stumps, II. P. JACOBSEN (West. Engin., 5 (1914), No. 5, pp. 202-204, figs. 8).—The author shows how to regulate hauling lines in connection with a logging engine so as to clear a wide area with a single setting of equipment. Statistics of capacity are given.

Heat power machines or electric motors? E. Jaenichen (Maschineu Ztg., 12 (1914), Nos. 17, pp. 193-197; 18, pp. 201-204).—The author reports considerable data for the purpose of comparing the efficiency and economy under actual working conditions of steam and internal combustion engines and electric motors for general use on farms in Germany.

A summary of the data indicates that the internal combustion engine is the most efficient type of power for the smaller work about the farm. For short working periods the benzine or benzol engine is the most efficient, while for the longer working periods the naphthalin engine is the most efficient. For the heavier work of threshing, etc., the steam engine usually gives better results, although it is stated that for stationary power plants of about 30 horsepower where the exhaust steam of a steam engine can not be utilized the Diesel engine is superior.

The data in general are not favorable to the use on farms of electricity from central stations, and it is concluded in this respect that owing to the high cost of electricity the time has not yet come for its general use on farms.

Tractor and horse power, W. DINSMORE (Breeder's Gaz., 66 (1914), No. 15, pp. 585, 586, fig. 1).—From observations of actual working conditions in the Northwestern States and in the Canadian northwest it is stated that for general farm operations the tractor has not proved successful from the standpoint of economy. Its most important use in those localities is said to have been the breaking of virgin prairie.

The use of tractors in Russia, F. De Condé (Jour. Agr. Prat., n. ser., 28 (1914), No. 27, pp. 23-25).—Some of the results of Russian tests of steam and internal combustion tractors plowing with disk and moldboard plows are given in incomplete form.

Plans and detailed description of new dairy barn at the college farm, A. S. Cook (New Jersey Stas. Rpt. 1913, pp. 346-354, pls. 8).—A dairy barn designed

to provide space for hay storage and stable room for 40 cows is described and illustrated.

The general plan is not elaborate and is said to be well adapted to practically any conditions where milk is produced. The construction is of hollow tile with stucco on the outside and plaster inside. It is stated, however, that the same general plan may be followed with lumber. The barn is 127 ft, long and 36 ft. 8 in, wide. The ventilating system is of the well-known King type. The foundation and first floor are constructed of 1:3:5 concrete.

The first floor is divided into three separate parts. One section is divided into box stalls for cows and calves and bull pens. Another section, in which there are two rows of stalls with the cows facing in, is devoted to milch cows. A third section contains the milking room and medicine room.

The first floor equipment consists of iron pipe stanchions and partitions, both in the stalls and in the pens. The stanchion is of the swinging chain type and the stalls are 3 ft. 6 in. wide. The mangers are of galvanized iron and may be raised or lowered. A litter carrier is installed to carry the manure to the pit but feed is handled on trucks.

Conveniences for handling the farm cow and her products (U. S. Dept. Agr., Office Sec. Spec. [Circ.], 1914, Dec. 31, pp. 6, figs. 10).—This circular, by means of discussion and diagrammatic illustrations, gives popular information regarding the cow stall, calf stanchion, milk cans, milk room and cooling box, water heater, and equipment for washing dairy utensils.

Worth and uses of silos and silage (Quart. Rpt. Kans. Bd. Agr., 33 (1914), No. 129. pp. 110–380, figs. 36).—Practical information is given on the value, making, and use of silage, the materials therefor, and features for the construction of the silos most approved.

Details of construction and cost of vitrified tile silo, A. S. Cook (New Jersey Stas. Rpt. 1913, pp. 334-344, pls. 5).—The details of construction of the vitrified tile silo are described and illustrated and cost data given. This type of silo is considered to be one of the most substantial and efficient of the types used at present. The total cost of such a silo erected at the station, 12 ft. in diameter and 32 ft. high, was \$603.83.

Steam power versus electricity for filling silos (*Elect. World*, 64 (1914), No. 19, p. 914, figs. 3).—A rural community found that the daily rent, including cost of energy consumption, of a 15-horsepower electric motor with transformers mounted on a truck when used for filling silos was considerably less than the expense of using a traction engine. The electrical outfit was rented for \$5 per day, while the actual total cost of steam-engine drive was about \$12.50 per day. The average energy required per ton for silo filling was said to be 1.17 kilowatt hours.

The effects of the acid of silage on concrete, A. S. Neale and W. S. Corsa (Concrete-Cement Age, 5 (1914), No. 3, pp. 125).—Both experimenters claim to have observed no injurious effects on the walls of concrete silos due to acids in the silage. It is stated that in case any bad effects are noticed washing with neat cement or coal tar dissolved in gasoline will overcome them.

Further studies in poultry house construction, H. R. Lewis and A. L. Clark (New Jersey Stas. Rpt. 1913, pp. 259-271, pls. 4, fig. 1).—This report describes and diagrammatically illustrates the so-called type L poultry house, known also as the New Jersey multiple unit laying house, developed at the station, and gives the results of studies of this and five other houses which are designated by the letters J. K, M, R, and P, and were described in a previous report (E. S. R., 30, p. 389).

Type J house is of the half monitor construction with an entire glass front in the peak and with the front left entirely open two feet above the ground and covered with inch mesh wire. Type K house is of the half monitor construction with glass front and no muslin curtains. Type M house is of the shed roof type 8 ft. 2 in. high in front and 5 ft. 2 in. at the back and is built of 12 by 12 in. Natco hollow tile. Type R house is intended for a cheap shelter and is of the shed roof type $7\frac{1}{2}$ ft. high in front and 4 ft. in the back. Each unit of the type L house is a square house 20 by 20 ft, and gives a capacity of 100 hens. The house is only single boarded on all four sides except at the rear and above the dropping boards and perches. About this space sheathing boards are also closely nailed to the side of the back studs and rafters. The front of the house is largely taken up by the curtains and windows, the former being hinged at the top and the latter at the side. A distinct feature of the house is a large dry mash hopper placed every 40 ft.

The studies were made for the purpose of securing data on cost of material, temperature variations, moisture conditions, food consumption, egg production, and total net profit.

It was found that a type resembling house L meets more nearly all the ideal conditions and that type K represents everything which is undesirable. As a result of the studies the houses are classed in the following order of excellence: L. R. J. P. M, and K.

In addition, the New Jersey portable breeding house is described and diagrammatically illustrated.

Cooking-boilers on poultry farms, J. Hadlington (Agr. Gaz. N. S. Wales, 25 (1914), No. 10, pp. 898-900, figs. 4).—These are briefly described and illustrated diagrammatically.

Ice houses and the use of ice on the dairy farm, J. T. Bowen and G. M. Lambert (U. S. Dept. Agr., Farmers' Bul. 623 (1915), pp. 24, figs. 18).—This discusses the use of ice on the dairy farm for the keeping of milk and cream and gives plans and specifications for ice houses.

It is pointed out that wherever ice is abundant the cost of harvesting and storing is usually very small. "The dairyman should consider both the cost of construction and the cost of the ice in selecting the type [of house] most suitable for his requirements."

As regards insulation it is stated that "an air space 1 in, wide is practically as good as one 12 in, wide. Air circulation is valuable, however, between the insulated ceiling and the roof of an ice house in order to break up the heat radiation through the roof. No entrance or exit of air should be allowed to take place in a room where ice is stored, especially at or near the ground line, as the cold currents of air at the bottom will filter through... The building should be so constructed that there will be a circulation of air through the outer walls and at the eaves to the ventilator on the roof, as these air currents tend to break up the heat radiation through the walls and roof...

"Ice should never be placed directly on the ground, soil being a fairly good conductor of heat, especially when wet.... In houses that have the floor below the level of the ground, sufficient drainage usually can be obtained through the soil, especially if the soil is porous. It may be necessary, however, with a clay soil, to excavate a foot or two and fill in with einders or gravel, and to place a 3-in, porous tile under the floor. This drain should be properly trapped or sealed to prevent warm air from entering the building through the floor....

"It is of the utmost importance that brick, concrete, and wooden buildings be waterproofed. Brick and concrete work may be rendered waterproof by painting the outside of the wall with white lead and oil or by coating the walls with a preparation of paraffin or asphalt. . . .

"About 40 cu. ft. of space should ordinarily be allowed for a ton of ice. . . .

"Under general conditions about 1 lb, of ice will be required to cool and keep 1 lb, of cream in good condition until delivered to the creamery when delivered are made three times a week. When storing ice about 50 per cent more should be packed than is actually needed. This amount allows for a heavy shrinkage and for household uses. The dairy farmer should provide annually $\frac{1}{2}$ to 1 ton of ice per cow for cooling cream only and $1\frac{1}{2}$ to 2 tons per cow if whole milk is cooled, depending upon the locality and other factors. If a cake of ice is kept floating in the water surrounding the cream cans when the ordinary cooling cans are used, the temperature will remain at about 40° F. Good icewater tanks can usually be constructed for from \$5 to \$20."

Ventilation of farm buildings, J. H. Grisdale and E. S. Archibald (Canada Expt. Farms Bul. 78 (1914), pp. 32, figs. 23).—This bulletin deals with the ventilation of cow and horse barns and piggeries and reports comparative studies of several systems of ventilation, including the Rutherford and King systems.

For the horse and cow barns it is stated that the Rutherford system has proved much superior to any other tried, while for piggeries the Rutherford and the modified Rutherford systems were both found to be uniformly satisfactory. The essential features of the systems recommended are described and diagrammatically illustrated.

Cooling two rooms in a country residence, A. M. Feldman (Heating and Fentilating Mag., 11 (1914), No. 3, pp. 33, 34, figs. 2).—Two rooms in a country residence were cooled by installing a cork-insulated box in the attic immediately above the rooms. The top of the box was connected with a short duct to the roof for taking in fresh air and the bottom was connected to the ceiling registers of the two rooms. Fresh air enters the top of the box, is cooled by coils from a small refrigerating plant for the pantry and kitchen, and drops by gravity through the registers to the floor of the rooms.

RURAL ECONOMICS.

A rural survey in southwestern Ohio, P. L. Voct (Miama [Ohio] Univ. Bul., 11 scr., No. 8 (1913), pp. 93, figs. 17).—According to the author, among the principal problems awaiting solution in the areas studied are the decrease in church membership, especially among young persons, a nonresident ministry, a lack of organized rural recreation, inadequate rural school equipment and teaching force, and the breaking up of the homogeneity of rural population through the growth of tenantry, increase of foreign population, and change in type of farm labor. Among the constructive tendencies noted were the gradual increase in rural culture and in interest in the problems of rural life and cooperative enterprises. The author suggests, as some of the changes to be brought about, the reorganization of the church and rural school system, the encouragement of farm organizations, the development of pride in rural life and institutions, and the provision for social and recreational life of the rural communities.

The Minnesota Crop Improvement Association (Ann. Rpts. Minn. Crop. Improv. Assoc., 8-11 (1911-1914), pp. 91. figs. 14).—This report contains abstracts from addresses made before the association, and relates principally to the effects of seed selection upon profitableness of farming and to the various agencies tending toward the improvement of rural conditions.

Practical community studies (Bul. Univ. Ga., No. 228 (1914), pp. 44).— This outline contains a limited syllabus of educational and social topics planned for elementary and preliminary studies in specific localites. The subjects are divided into those primarily urban and rural and those relating to general social problems and to sociological theory. Social and civic work in country communities, ELLEN B. McDonald, Ros. M. Cheney, and G. F. Comings ([Wis, State Supt. Pub. Instr.] Bul. 18 (1913), pp. 138, figs. 29).—This bulletin is the report of a subcommittee appointed to investigate conditions in the rural schools of Wisconsin and treats of the relationships between the home, the school, and the community, and outlines methods for making these relationships effective and helpful along the lines of community improvement.

Agricultural survey, 1913, F. C. Nunner (Com. Conserv. Canada Rpt., 5 (1914), pp. 142-174, pls. 4).—The committee on lands of the Canadian Commission on Conservation conducted agricultural-survey work in 29 districts in Canada and noting the crops grown, rotations followed, seed selection, manures used, insect and plant diseases, fuel, power and water supply, and live stock and labor conditions. These pages give the details by districts.

Full report of the Royal Commission on Agriculture (Brit. Columbia Rpi Roy. Com. Agr., 1914, pp. 1X+398, figs. 3).—Part 1 of this report discusses conditions in British Columbia as they relate to the public and private lands land and public improvements, taxation, labor, agricultural credit, marketing and cooperation, and agricultural education, and contains a summary of the hearings held by the commission in various points in the Province. Part 2 describes the agricultural conditions and types of farming in British Columbia and cooperation and agricultural credit in European and other countries.

Annual report on the working of cooperative societies in the Bombay Presidency, 1914 (Ann. Rpt. Work. Coop. Soc. Bombay Pres., 1913–14, pp. H+78+3).—This report reviews the progress made and outlines the working of the central societies and unions of the agricultural and nonagricultural societies and other forms of cooperation in the Bombay Presidency. Statistical tables are given showing membership, receipts and disbursements, assets and liabilities, and profit and loss of individual societies.

The farmers' elevator movement, I, II, O. N. Refsell (Jour. Polit. Econ. 22 (1914), Nos. 9, pp. 872-895; 10, pp. 969-991).—The author describes the various methods of selling grain through elevators and track buyers, the alleged methods used by line elevator companies to drive the independent farmers' elevators out of business, and the methods that have been devised to meet their competition at Rockwell, Iowa. The farmers at this place formed an elevator company, the by-laws of which contain a penalty clause which provides that members are to pay into the treasury of the company $\frac{1}{2}$ per cent bushel for every bushel of grain sold either to the company or to its competitors. By the means of this payment the company has been able to exist in spite of all outside competition. This system became somewhat of a model for other farmers' elevator companies. Later, it is stated, boycotted commission firms. because of the harmful effect produced on their business by the work of the regular grain trade, began to cooperate actively with the farmers' elevator companies to bring about a more rapid spread of the movement. State associations were formed which accelerated the building of this kind of elevator and gave additional strength to the individual company. The author points out various methods said to have been used in attempting to force the new type of company out of business.

Farmers' market bulletin (Farmers' Market Bul. [N. C.], 2 (115), No. 1, pp. 26).—This is a continuation of the series previously mentioned (E. S. R., 31, p. 894) and contains a partial list of merchants who purchase produce outside of the State and the commodities handled by each, and a partial list of farmers with farm products for sale indicating quantity and kind.

Money crops in place of cotton, E. R. Kone (Texas Dept. Agr. Bul., n. ser., No. 13 (1914), pp. 27, pl. 1).—This bulletin outlines a system of farming for the different sections of Texas designed to give the farmer practical money crops and a source of revenue which may be in part a substitute for cotton.

Cost of grain production in Canada, 1913 (Census and Statis, Mo. [Canada], 7 (1914), No. 76, pp. 239-396).—A special inquiry, conducted through the cropreporting correspondents, as to the cost of grain growing in Canada is reported, with data as to the cost of the various items for fall and spring wheat, oats, barley, flax, and corn in the various Provinces.

The movement of prices during recent years, A. Mariotti (Atti. R. Ist. Incorogg. Napoli, 6, ser., 65 (1913), pp. 183-250).—The author compares the index of prices of the principal agricultural products in England, Germany, France, Belgium, the United States, and in the city of Naples. The principal part of the discussion relates to changes since 1900

Return of prices of crops, live stock, and other Irish agricultural products (Dept. Agr. and Tech. Instr. Iveland, Agr. Statis, 1913, pp. 79, pls. 17, fig. 1).—This report contains information along the lines previously noted, but with reference to 1913 (E. S. R., 39, p. 297).

The agricultural outlook (U. 8. Dept. Agr., Farmers' Bul. 645 (1914), pp. 45, figs. 2).—This issue contains the final estimates in detail for the crop year 1914. The total area harvested for 14 crops for which estimates are included was 300,782,000 acres and comprised 92 per cent of the entire cultivated area of the United States and being 0.1 per cent larger than in 1913 and 2.4 per cent larger than in 1912. The total production was 10 per cent larger than during 1913 and 6 per cent smaller than for 1912. The average value per acre of these crops was \$16.44 for 1914, \$16.52 for 1913, and \$16.15 for 1912, and the total values were \$4,946,000,000, \$4,966,000,000, and \$4,759,000,000, respectively. The estimated value of all crops was \$6,944,480,000, \$6,132,750,000, and \$5,842,220,000, respectively, and of animals and their products \$3,828,456,000, \$3,656,866,000, and \$3,500,570,000, respectively.

It is estimated that the cotton States on the average produce 46 per cent of their total wheat requirements, S6 per cent of their corn, 75 per cent of their oats, and 79 per cent of their hay. To produce the remainder would require 15,000,000 acres.

The purchasing power of the farmer is discussed by N. C. Murray. It is estimated that from 1899 to 1909 the money value of one acre of the farmer's crops increased 72.7 per cent but in the same period the money value of the articles usually purchased by the farmer increased 12.1 per cent. In 1913 the value of one acre of the farmers' crops averaged about 1.2 per cent higher than in 1909, but the value of articles purchased by the farmer has advanced in the same time about 5.7 per cent.

Among the other phases of crop statistics discussed were the winter wheat and rye sowing and condition, the apple crop, a forecast of sugar production in Louisiana, onion and cabbage statistics, trend of farm prices, shipments of California barley to New York, cold-storage holdings of apples, and the wheat crop of the southern hemisphere.

Statistical tables are included showing the estimated acreage, yield per acre, total production, average price and value December 1 for the principal crops for 1914, with comparative data for earlier years. Additional statistical tables are included relating to subjects discussed in the text.

Agricultural statistics of Denmark (Statis. Aarbog Danmark, 19 (1914), pp. 26-29, 36, 44-52).—This yearbook contains information along the lines previously noted regarding agricultural work and the number of farms in Denmark, including data for 1913 concerning the use of land (E. S. R., 30, p. 392).

Census of agriculture in Greece (*Recense*, Agr. tiréve, 1941, pts. 1, pp. XVI+1-14II; 2, pp. $VIII+14\beta-267$).—These reports give statistics showing by Provinces the area in crops for 1911 for Thessaly, Arta, and the Ionian Islands.

AGRICULTURAL EDUCATION.

Agricultural education, R. II. Formes and A. M. McOmie (Arizona Sta. Rpt. 1913, pp. 286-296).—An account is given of the scheme of agricultural education in Arizona, comprising academic courses in high and normal schools and the state university; extension instruction, including a demonstration train, a two weeks' farmers' short course held annually at the university, and farmers' institutes; and advisory relations, including correspondence between the station staff and farmers, and a farm management service in process of organization.

Fifth annual report of the eleven district agricultural schools of Georgia, J. S. Stewart (Bul. Ga. State Col. Agr., 2 (1914), No. 13, pp. 35, figs. 4).—This report contains reports of these schools, including an outline of the course of study, and tables showing the enrollment, expenses, equipment, farm products, etc.

The training and certification of teachers for agricultural, industrial, and household arts subjects in the public schools of Indiana, W. F. Book (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 5 (1914), pp. 36).—The author discusses the need of trained teachers for pre-vocational work, the general character and aim of the work, qualifications and training of teachers and agencies available for training them, and standards that must be met by schools offering training courses in pre-vocational subjects, and outlines summer school work, profitable courses for principals and superintendents, and teachers' training courses in domestic science and industrial arts.

Tentative course of study in industrial subjects for the public schools of Indiana (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 2 (1913), pp. 203).—This bulletin discusses the aim, scope, and problems of vocational work in the public schools of Indiana; offers general suggestions and helps in conducting this work in the grades from the kindergarten through the high school and in special departments and schools, and tentative outlines for work in agriculture, domestic science, and industrial arts; and gives lists of suggestive references on vocational and industrial education and of equipment.

Report of agriculture in the high schools of Michigan, W. H. French (Mich. Agr. Col., Dept. Agr. Ed. Bul. 13 (1914), pp. 14, pl. 1, figs. 9).—This bulletin gives brief reports on the agricultural work in Bay City. Escanaba, Manistee, and Muskegon, home projects, the Houghton Township School, the effect of teaching agriculture on the school and community, boys' and girls' club work, and general suggestions as to means and methods of improving the work in agricultural instruction in the high school. A statistical table shows that 31 high schools offered one or more years of agricultural work to 1,000 boys and 356 girls, and approximately 500 boys and girls worked at home projects during the summer of 1914. Seventeen schools offered one-week courses for farmers and 16 had a total of 31 boys' and girls' clubs.

Twenty-first annual report of the inspector of state high schools of Minnesota, G. B. Aiton (Ann. Rpt. Insp. State High Schools Minn., 21 (1914), pp. 51).—For the year ended July 31, 1914, 119 high schools received a total state aid of \$237,853 for instruction in agriculture. Agriculture was taught in 134 high schools, cooking in 165, and sewing in 179 to 4,053, 5,799, and 6,680 students, respectively. The total expenditure for agricultural equipment was \$40,558.

and for cooking and sewing equipment \$55,144. Statistical tables show the enrollment and expenditures for agriculture and home conomics instruction.

Vocational education in Pennsylvania (Penn. Dept. Pub. Instr., Vocational Dir. Bul. 1 (1913), pp. 27).—This bulletin contains the text of the law enacted in 1913 providing state aid for vocational, industrial, agricultural, and household arts schools and departments, an interpretation of the law, rules and regulations to be applied, methods of putting the new statute into effect, etc.

Agricultural schools and departments (Penn. Dept. Pub. Instr., Vocational Div. But. 2 (1913), pp. 15).—This bulletin discusses conditions and requirements with reference to organization, qualifications of teachers, courses of study, project work, summer employment of teachers, use of land, rooms and equipment, etc., governing agricultural schools and departments desiring to qualify for state aid.

Household arts schools, departments, and evening classes (Penn. Dept. Pub. Instr., Vocational Div. Bul. 4 (1913), pp. 18).—This bulletin considers in detail those parts of the vocational education law of Pennsylvania that relate to household arts education, including suggestive outlines and a description of 4-year, 2-year, and evening courses, and a plan of precedure for organizing evening classes.

Correlating agriculture with the public-school subjects in the Southern States, C. H. Lane and E. A. Miller (U,S,Dept,Ayr,Bul,132,(1915),pp,44,pgs,9).—The authors present a scheme by means of which the rural or public school teacher may utilize clubs in correlating agriculture and farm-life problems with the regular school work. For the purpose of this scheme public school classes are divided into two groups, including grades 1 to 5 and 6 to 8, respectively. The subject matter outlined is arranged according to a monthly sequence plan, 9 months' work being provided for. Directions are included for organizing boys' and girls' clubs, securing literature, selecting, storing, and testing seed, planning school gardens, and making school exhibits, including score cards. Suggested problems in arithmetic are added,

Course of study in agriculture for the public schools of Oregon, F. L. Griffin (Salem, Oreg.: State Dept. Ed., 1914-15, pp. 79).—An agricultural course for the eighth grade is outlined in seasonal sequential order. It comprises a series of lessons of from 20 to 30 minutes each a day in orchard, field, and garden crops, beneficial and injurious insects, plant diseases, weeds, poultry husbandry, dairying, animal husbandry, farm management and machinery, forestry, and the country home and its surroundings. The lessons are accompanied by suggestions and directions for practical exercises, at least one for each week. A list of references is included.

Outlines of nature study and elementary agriculture, M. J. Abbey (Salt Lake City: Univ. Utah, 1913, pp. 103).—In this bulletin the author discusses the correlation of nature study with other school subjects, and outlines the work in nature study and elementary agriculture, including typical lessons from the first to the eighth grades, inclusive. The course in elementary agriculture for the seventh and eighth grades may also be used, with slight modifications, as an elementary high school course.

Agriculture in elementary schools (Augusta, Me.: Dept. Ed., 1914, pp. 28).— This circular contains an outline for the study of school and home gardening, together with laboratory exercises, exercises in soils and plant growth for the rural schools in Maine, and suggestions concerning the organization of boys' and girls' agricultural clubs.

Helps for teachers in agriculture: Soils, M. L. FISHER (Purdue Univ. Dept. Agr. Ext. Bul. 31 (1914), pp. 12).—The author outlines soil studies for the seventh and eighth grades of the Indiana public schools for 1914–15.

Helps for teachers in agriculture: Farm crops, M. L. FISHER (Purdue Univ. Dept. Agr. Ext. But. 30 (1914), pp. 12, figs. 7).—Corresponding to the above, this bulletin gives a brief discussion, with suggestions for laboratory and field work, of wheat seeding, nectules of legimes, wheat stooling and the Hessian fly. rotations, cowpeas and soy beans, oats, potatoes, and corn growing.

Helps for teachers in agriculture (Dept. Pub. Instr. [Ind.], Ed. Pubs. Bul. 12 (1914), Vocational Ser. 7, pts. 1, pp. 14; 2, pp. 14).—This bulletin comprises two leadlets which contain detailed outlines for the months of September to December, inclusive, on Soils and Poultry, prepared by Z. M. Smith. Horticulture and Dairying, by J. D. Harper, and Animal Husbandry and Crops, by F. M. Shanklin. No one teacher is expected to use all the material outlined, each county superintendent of schools selecting one or two subjects for his county.

Laboratory exercises in farm mechanics for agricultural high schools, D. Scoates (U. S. Dept. Agr., Farmers' Bul. 638 (1915), pp. 26, figs. 26).—These exercises in rope work, farm power, farm buildings and machinery, surveying, tile drains, terracing, irrigation, and roads, are suggested to serve as a guide to the teacher of high school agriculture. Brief notes are given on library and laboratory equipment.

Planning and serving meals, Neale S. Knowles and Louise H. Campbell (Iowa State Col. Agr. Ext. Dept., Home Econ. Circ. 1 (1913-14), pp. 29. figs. 7).—This circular contains a study of the nutritive value of foods; suggestions with regard to the choice of foods to suit the needs of the family, preservation and public care of foods, and serving meals; and a price list of kitchen utensils.

Home furnishing, Winifred A. Gettemy (*lowa State Col. Agr. Ext. Bul. 17* (1913), pp. 36. figs. 19).—The author discusses the construction of a house and its decoration and furnishing.

Textiles, Neale S. Knowles and Louise H. Campbell (Iowa State Col. Agr. Ext. Dept., Home Econ. Circ. 2 (1913–14), pp. 16, figs. 7).—This is a study of textiles including classification, structure of fibers, characteristics, tests, and methods of adulteration of cottons, lineus, woolens, and silks, methods of removing stains, width of textiles, some points in selecting textiles, the Consumers' League, and references for study.

Home economics study classes, ROBERTA MCNELL (Purdue Univ. Dept. Agr. Ext. Leaflet 54 (1914), pp. 6, fig. 1).—This leaflet gives suggestions for organizing home economics study classes among farm women "to help each other to make better homes and to have more joy in living."

Suggestions for household exhibits (Iowa State Col. Agr. Ext. Dept., Home Econ. Circ. 4 (1913-14), pp. 8, fig. 1).—Entries and score cards are suggested.

School exhibits, II. E. ESWINE and TREVA KAUFFMAN (Agr. Col. Ext. Bul. [Obio State Univ.], 9 (1914), No. 9, pp. 16, figs. 15).—The authors suggest agricultural and home economics material suitable for display at school exhibits and how best to select and prepare specimens.

Boys' and girls' home economics clubs, Laura Comstock and Ethel H. Nash (Mass. Agr. Col., Dept. Agr. Ed. Circ. 30 (1914), pp. 40, figs. 9).—This is a program of instruction in home economics club work, including cookery, canning and preserving fruit and vegetables, table serving, sewing, darning or mending, and other household activities.

Nebraska boys' and girls' clubs, Course I, twelve lessons on foods and their preparation, Orpha E. Nesbir (Univ. Nebr., Col. Agr. Ext. Bul. 17 (1913), pp. 80, figs. 3).—One lesson in foods and their preparation is outlined for each month in the year for girls' clubs. Most of the work is done by the girls at home.

Nebraska boys' and girls' clubs, Course I, twelve lessons in sewing, Mary E. Brown (Univ. Nebr. Col. Agr. Ext. Bul. 16 (1913), pp. 55, figs. 29).—The author outlines 12 lessons in sewing corresponding to the above.

Organization of Nebraska boys' and girls' clubs, Huldah Peterson (Univ. Activ. Col. Agr. Ext. Bul. 10 (1913), pp. 12. figs. 2).—This bulletin contains suggestions for organizing local, county, state, and national clubs, including a local constitution and outlines of boys' and girls' club work for 1913.

Report of the department of agricultural extension, A. AGEE (New Jersey Stas. Rpl. 1913, pp. 379-383).—The organization and work of the department of agricultural extension of the New Jersey State Station, established December 1, 1912, are described.

The agricultural college brought to the farm (Facts for Farmers [Mass, Agr. Col.], 5 (1914), No. 2, pp. 4).—Some of the most important lines of extension work being conducted by the Massachusetts Agricultural College are briefly outlined.

MISCELLANEOUS.

Twenty-fourth Annual Report of Arizona Station, 1913 (Arizona Sta, Rpt. 1913, pp. 233–296, pl. 1, figs. 3).—This contains the organization list, an administrative report by the director on the work and publications of the station, a financial statement for the fiscal year ended June 30, 1913, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue.

Annual Report of New Jersey Stations, 1913 (New Jersey Stas. Rpt. 1913, pp. XXVIII+815, pls. 97, figs. 11).—This contains the organization list of the stations, a financial statement for the State Station for the fiscal year ended October 31, 1913, and for the College Station for the fiscal year ended June 30, 1913, a report by the director, and departmental reports, the experimental teatures of which are for the most part abstracted elsewhere in this issue. Reports of the fertilizer inspection have been noted in Bulletins 259 (E. S. R., 30, p. 327) and 261 (E. S. R., 31, p. 126), and feeding stuffs in Bulletin 256 (E. S. R., 29, p. 665) and the text of the lime-inspection law.

Reports of the Edgeley, North Dakota, substation, 1905–1913, O. A. Thompson and J. H. Shepperd (North Dakota Sta., Rpts. Edgeley Substa, 1905, pp. 20, pls. 2; 1906, pp. 30, pls. 5; 1907, pp. 38, pls. 9; 1909, pp. 55, figs. 6; 1916, pp. 47, figs. 15; 1912, pp. 50; 1913, pp. 20).—These reports give data as to temperature and rainfall and brief summaries of the lines of work at this substation during the periods indicated. The experimental work reported is for the most part abstracted elsewhere in this issue.

Annual Reports of the Langdon, North Dakota, substation, 1909–1913, E. D. STEWART and J. H. SHEPPERD (North Dakota Sta., Rpts. Langdon Substa. 1909, pp. 12; 1910, pp. 19, figs. 4; 1911, pp. 29, figs. 5; 1912, pp. 32, figs. 6; 1913, pp. 26, figs. 4).—These reports give brief summaries of the lines of work at this substation during the periods indicated. Those for 1911, 1912, and 1913 also contain meteorological data. The experimental work reported is for the most part abstracted elsewhere in this issue.

Twenty-seventh Annual Report of South Carolina Station, 1914 (South Carolina Sta. Rpt. 1914, pp. 33).—This contains the organization list, a report of the director on the work and publications of the station, a financial statement for the fiscal year ended June 30, 1914, and departmental reports, of which that of the horticulturist and the botanist and plant pathologist are abstracted elsewhere in this issue. The report of the association agronomist contains brief cultural notes on cotton, Fulghum oats, Sudan grass, Abbruzzi rye, and beardless barley.

NOTES.

Connecticut College.—According to a note in *New England Homestead*, a requirement of at least three months of actual farm work of approved grade before graduation has been adopted. Paul W. Graff, a graduate of the college, has been appointed assistant in botany.

Kansas College.—A scholarship of \$300 per year has been offered by L. M. Crawford, of Topeka. The scholarship is to be in the division of general science, the donor's preference being that its holder elect courses chiefly in agriculture, if a man, and in home economies if a woman.

Massachusetts College.—A major in rural journalism has been authorized, beginning with the fall semester.

The enrollment at the winter school reached 180. Of these 25 per cent had attended or graduated from other colleges.

Minnesota University and Station.—The appropriations requested for the university for the ensuing biennium aggregate \$3,212,450, of which 35 per cent is for the agricultural work. Among the items is one of \$45,300 to enlarge and equip the new home economics building, which is already proving inadequate to accommodate the 515 students registered.

Howard R. Smith, professor of animal husbandry and animal husbandman, has resigned to become live-stock lecturer and specialist for a national bank in St. Paul.

Nebraska University and Station.—Under an act passed by the last legislature about \$700,000 will be available for the erection of agricultural buildings and equipment during the next four years. Plans for a dairy building have been completed, and an agricultural engineering building approximately 200 feet square is under consideration.

The agricultural science group in the college curriculum has been superseded by a general agricultural group, the first two years of which are prescribed and the remainder largely elective. Beginning next September students may take the entire college course at the university farm, or, if preferred, the academic and general science studies may be taken at the university. The agricultural practice group has also been rearranged and shortened to two years by the elimination of practically all nonagricultural subjects. A certificate of proficiency in farm practice is to be awarded at the completion of this course to students sufficiently experienced in practical farm work and to others on complying with practice requirements on farms. It is expected that this change will make it unnecessary for high-school graduates to enter the school of agriculture, and by providing practical farm training at once will greatly increase the registration in the college of agriculture.

Dr. Charles Edwin Bessey, head of the department of botany and head dean and distinguished as a leader in botanical education and research for many years, died February 25 at the age of 70 years. Dr. Bessey was born on a farm at Milton, Ohio, and graduated from the Michigan College in 1869. He received the M. S. degree in 1872 from the same institution, that of Ph. D. from the State University of Iowa in 1879, and that of LL. D. from Iowa College in 1898. He also studied two years with Dr. Asa Gray, of Harvard University.

Dr. Bessey's long career as a teacher began in 1870, when he was appointed professor of botany at the Iowa State College. He remained in this position

until 1884, also serving for a time as acting president. In that year he went to Nebraska us professor of botuny, also serving as acting chancellor at various periods and as head dean since 4909.

In addition to these duties Dr. Bessey was botanical editor of the American Naturalist from 1880 to 1897 and of the same department of Science since 1897. He was president of the American Association for the Advancement of Science in 1910–1941; the Botanical Society of America, 1895–1896; Society for the Promotion of Agricultural Science, 1889–1891; the Department of Natural Science of the National Education Association, 1895–1896; and the American Microscopical Society in 1902; and was a member of a long list of other associations. He was the author of several books, including Botany for High Schools and Colleges, 1884; Elementary Botanical Exercises, 1892; Elementary Botany, 1904; and Plant Migration Studies, 1965, as well as of a large number of scientific papers and reviews.

Dr. Bessey's services to the university were of unusual importance, and have had an enduring influence on its development. He was a strong believer in the necessity of the broadest essential preparation of agricultural workers. In his long service he trained many botanists of prominence in this Department and elsewhere, and as a recent tribute states "their achievements form the greatest monument that can be erected to his memory. Present-day students will do well to remember that the success of his students is in large part due to the scientific spirit with which he has imbued them."

New Jersey College and Station.—Recent appointments include Erwin C. Van Leer as assistant herdsman in the dairy department, vice John W. Bartlett, who has been made field assistant in horticulture in place of Joel P. Sherman, resigned, Roscoe W. De Baun as extension specialist in market gardening, and Winifred N. Cowgill as field assistant in horticulture. The death of the college and station treasurer, Irving S. Upson, is noted.

Pennsylvania College.—The *Penn State Farmer* announces that a farmer's week held in Philadelphia was attended by over 800. A similar program for Pittsburgh is under consideration.

South Carolina College and Station.—The legislature has elected B. H. Rawl of the Dairy Division of this Department, to succeed W. D. Garrison, resigned, as a member of the board of trustees.

W. W. Fitzpatrick, formerly of the farm improvement department of the Southern Railway, has been appointed assistant dairyman in charge of field demonstrations in South Carolina, with headquarters at the college.

As one of its Smith-Lever projects, the extension division is organizing cooperative cream routes in near-by counties. The cream is shipped to the coltege, manufactured into butter, and marketed for the farmers. The plan has proved successful in its first six months, and recently egg gathering has been begun on the routes. The dairy equipment has been increased by the installation of a churn of 600 lbs. daily capacity.

Tennessee University and Station.—The will of the late Colonel Benjamin Rush Strong, a resident of Knoxville, contains bequests to the university of \$35,000 for the purchase of additional land for the station, \$30,000 for a girls' dormitory, and a business house in Knoxville, the income from which is to constitute a medal fund for the university and certain other institutions of tearning. It also provides that the residue of the estate from these and many other bequests is to be given to the university as a trust fund for loans to deserving students of the agricultural department. The amount available for this loan fund is not definitely known, but is estimated at from \$200,000 to \$400,000.

EXPERIMENT STATION RECORD.

Vol. XXXII. May, 1915. No. 7.

A notable publication has been issued from the Ohio Experiment Station which on account of an attitude it represents is worthy of special comment. It is entitled A Review of the Literature of Phosphorus Compounds in Animal Metabolism, and is the work of Dr. E. B. Forbes and Miss M. Helen Keith. It is a highly important contribution to our literature of agricultural investigation, and one which not only the authors and the station issuing it but the American system of stations may well be proud of. The lesson it carries in the preparation for research has wide application.

Soon after Dr. Forbes went to the Ohio Experiment Station eight years ago, he began a series of investigations into the relations of mineral constituents in animal nutrition. Although these studies are of quite technical character and do not insure direct practical results at once, he has been supported in his undertaking and has gradually secured facilities for the work which are hardly equaled anywhere.

The broad interest of agricultural science in the whole question of the mineral elements lies, as Dr. Forbes explains, "in that larger intermediary metabolism between the soil and the sea which begins with the weathering of the rocks, includes the whole of plant and animal metabolism, and ends with the formation of new rocks."

In its relation to animal life, phosphorus stands out as an unusually conspicuous member of this group. No other inorganic element enters into such a diversity of compounds and plays as important a part in so many functions. "Structurally, it is important as a constituent of every cell nucleus and so of all cellular structures; it is also prominent in the skeleton, in milk, in sexual elements, glandular tissue, and the nervous system. Functionally, it is involved in all cell multiplication, in the activation and control of enzym actions, in the maintenance of neutrality in the organism, in the conduct of nerve stimuli, and through its relation to osmotic pressure, surface tension, and imbibition of water by colloids it has to do with the movement of liquids, with the maintenance of proper liquid contents of the tissues, with cell movements, and with absorption and secretion."

The study of the mineral elements in relation to nutrition is a subject but recently taken up by our stations, and the large measure of the world investigation bestowed upon it has been reported since the

beginning of the present century. It extends back, however, for as much as two hundred years, and the literature of the last fifty years is quite voluminous. From the fact that the subject has been approached from the medical and the physiological, as well as the agricultural and nutrition standpoints, the papers relating to it are unusually widely scattered.

At an early stage Dr. Forbes' studies naturally led him into the literature, and showed how difficult of access and study it was in its widely diffused condition. With an industry and zeal which deserve to be highly commended he instituted a systematic search for original articles bearing on the subject of investigation, which soon developed into a large undertaking. The assistance of several competent persons was obtained in abstracting, and the search was organized to be carried on at various libraries and institutions over the country. The work was in active progress for several years, and the bulletin now published is the result, the data being compiled and digested by Dr. Forbes after it had been assembled from various sources. In scope and size it surpasses all expectations of those who had known of its progress—a volume of seven hundred and fifty pages, with the abstracts grouped by topics, accompanied by concise summaries, a bibliography of approximately twenty-five hundred titles cited in the text, referring to work ranging in date from 1719 to 1914, and concluding with a detailed index.

The review will not only aid Dr. Forbes in his studies, but it will be well-nigh indispensable to those engaged in work in this field or who may enter upon it. It will at once take place as a standard work and become a starting point for future investigation in this and related lines. It will serve from now on to make investigation more clearly directed and more effective. It would be surprising if it did not stimulate research in this general subject, for it opens up the field in a most attractive way, making apparent not only the progress which has been attained but the gaps that remain to be filled.

The publication of this monumental work represents a broadminded, liberal attitude, which stands for the community of interest in investigation and seeks its advancement rather than personal advantage.

When an investigator takes the pains to collect and digest the literature of his chosen field, as a part of a general program of experimentation in that field, we feel that he has gone at his work aright and commend him for his determination to build upon the foundation laid by the work of others. And when an experiment station not only authorizes the time and other expense for such a review of the past, but in addition publishes it for the benefit of the

603 EDITORIAL.

world, we commend the courage of its convictions and feel a new assurance that agricultural investigation at the experiment stations is not to be bound by any narrow view or impatient demand. an attitude evidences a deep appreciation of research as thorough and enlightened as present knowledge permits. It shows a determination not only to make its work thorough but constructive, adding to the sum of knowledge not by duplication but by building upon what has already been found.

Of course only a station liberally provided with means could undertake so comprehensive a piece of work. Usually the investigator will need to compile the literature, if at all, only in a narrow field relating to the project on which he is working. Regard must be had for the fitness of things and for the proper proportions at all times. And if this work had stopped with the making of a compilation and critical digest it would be less worthy of an experiment station, but it formed a real part of a line of investigation in which Dr. Forbes has already made notable progress. The compilation is not an end in itself but its evident purpose is to clear the field as far as practicable, in order that the author and other investigators may know just the status of investigation in that field and so be better prepared to do thoroughly constructive work.

The review has given not only the results but the point of view and the method of attack which others have developed, and has furnished the basis for a critical examination and comparison to show the sources of error in investigation and in reasoning. Thus in a large way it takes advantage of the accumulated experience of many individual workers. By this means theories, views, and plans become crystallized and perfected.

A clear vision and purpose is the first great essential in investiga-The aim is what gives the work direction and largely determines its quality. A clear conception of the purpose of agricultural experiment and investigation will not be satisfied with a superficial attack or an aim which does not sight beyond what is already known, or what last year's results showed, or the empirical facts they established in a large way. Hence, the spirit of Dr. Forbes' review applies to our experimental work as a whole. This is its broader application.

We have reached a point in experiment station work where it is more pertinent than ever that more attention should be given to making the work progressive in aim if not always in actual attainment. We need to define clearly the end of real experiment and the beginning of demonstration. Each new piece of work which is undertaken. whether it be of experimental grade or research, has the advantage of accumulated experience and results out of which method, fact, and theory have developed. It is reasonable to expect, therefore, that it

should be better, more scarching, and more conclusive than what has preceded it. How else can the expenditure of time and money be warranted, or the rightful ambitions of the investigator be satisfied?

Of course, we must find out whether what we know is true, but this usually implies more than simple repetition unless we are dealing with tradition. What we know is a product of reasoning from what has been definitely found out, and this at best is uncertain when our knowledge is in a transition stage, as much of it is which relates to agriculture. But the purpose of investigation is advancement, whether it be in extending the boundaries or in checking up what has been accepted as true. In either case it will not be characterized by duplication or repetition, but by a new point of view or method of attack.

The French scientist Berthelot once said, "If each of us adds something to the common domain in the field of science or art or morality, it is because a long series of generations have lived, worked, thought, and suffered before us." And an American scientist has enlarged upon this idea in defining the means by which knowledge grows: "Piece by piece must new truths be found and correlated. Each investigator must rest his work upon that of others. He must stand on the shoulders of the past if he is to look into the future. To know what has gone before is only possible where accumulated records are at hand."

Recognition of this has been the leading motive in preparing and issuing this journal, as a world review of new literature in agricultural science,—to enable the workers in that field to have access to the latest work and theory relating to their field. But research in agriculture is now reaching out so far into the basic sciences that no single abstract journal can meet all its needs, and other aids are necessary. This is the justification for spending money given for investigation in the purchase of scientific journals and books, and in their proper care.

As experimentation progresses we not only discover new phenomena, but in those we thought we knew unforeseen aspects reveal themselves. This is notably true in agricultural investigation. A thorough study of the experiments, even the simpler ones, if properly framed, reveals new facts or new means of advancement. Unless they receive adequate study or are builded on previous findings they become a round of mechanical routine, devoid of the prime essentials of productive experimentation.

It is sometimes advantageous to pause in doing and consider the nature of the end product. The experiment or the series of trials may meet all the accepted rules of procedure and follow the usual channels, but will they add another link in the chain of evidence or

EDITORIAL. 605

simply more data of the same kind? Unless the former is the case the work will not be genuinely constructive; and at the present stage this may well be the test. If its aim is not constructive it is on doubtful ground; and if its method and attack are not such as to lead to advancement, it lacks the degree of efficiency which may now rightfully be expected.

It sometimes seems that even now the force of this is not fully appreciated, partly no doubt because the field and function of the experiment station is still confused with that of demonstration, and some of its workers from their relations or inclinations vacillate from one to the other without changing their viewpoint. The effects of this are seen particularly in the simpler experiments, which should aim at advancement and conclusion, but which often represent merely repetition and duplication, ending mainly in demonstration. These simpler experiments ought to mark a contribution, not merely to what their author knows but to what is generally known; and if they do not afford promise of such a result in their plan and method it is questionable whether money so much needed for productive work should continue to be assigned to them. Too often they are undertaken without a search of the available literature to learn what others have found, and hence they involve nothing new in conception or result. There should be a means of determining in advance the character and the reasonable prospects of each undertaking, whether it be a piece of investigation or a relatively simple field experiment.

Some of our experimental work has moved in circles. It has been done more from the demonstration standpoint than from that of acquiring information. The attitude and aim are not genuinely experimental but rather of convincing the farmer by example and improving his methods because the need of it is keenly felt. No one questions but it has had good effect, and it has often been done in response to state appropriations secured specifically for that kind of work, because the response to it was easier to arouse. But one effect of this has been to not only confuse the public but worst of all the staff of the station. It has put them in a wrong position as station men and their work in a false light as station work. It has often kept them from the opportunity for more advanced and progressive work, and has sometimes blinded them to the real character of what they were turning out.

Now that extension work is definitely organized and provided for, the purpose of the experiment station and its place in the institution should be made clear and maintained. Demonstration for the purpose of teaching and experimentation for the purpose of learning should not be confused, and each should be made in the highest degree effective.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Studies relating to the chemistry of milk and casein, L. L. VAN SLYKE and A. W. Bosworth (New York State Sta. Tech. Bul. 37 (1914), pp. 11; Jour. Biol. Chem., 19 (1914), Nos. 1, pp. 67-71, 73-76; 3, pp. 397, 398).—This bulletin consists of three parts, as follows:

1. The cause of acidity of fresh milk of cows and a method for the determination of acidity (pp. 4-6).—"The acidity of fresh milk is due to the presence of acid phosphates. Titration of phosphoric acid with alkali, in the presence of calcium salts, results in hydrolysis of dicalcium phosphate formed during the titration, whereby free calcium hydroxid and phosphoric acid are first formed and then calcium hydroxid unites with more dicalcium phosphate to form insoluble tricalcium phosphate. As a result of these reactions more alkali is required to make a solution, containing calcium and phosphoric acid, neutral to phenolphthalein than is required in the absence of calcium. The calcium must be removed previous to titration by treatment of 100 cc. of milk with 2 cc. of saturated solution of neutral potassium oxalate 4."

II. The phosphorus content of casein (pp. 7-10).—"The amount of phosphorus in casein has been commonly given as about 0.85 per cent. By treating a solution of casein in dilute NH4OH with ammonium oxalate and an excess of NH₄OH and letting stand 12 hours the phosphorus content is reduced to about This lower percentage can not be explained as being due to 0.7 per cent. hydrolysis of casein and splitting off of phosphorus. While some of the casein is hydrolyzed, this portion does not enter into the final preparation and does not affect its composition, because the hydrolyzed portion is not precipitated by acetic acid while the unhydrolyzed part is. The higher figure ordinarily given is due to the presence of inorganic phosphorus (dicalcium phosphate) carried from the milk into the precipitated casein and not entirely removed under the usual conditions of preparation. The lower figure corresponds very closely to two atoms of phosphorus (0.698 per cent) in the casein molecule. Analyses of various preparations of casein containing varying amounts of ash show a general correspondence between the ash and phosphorus content."

III. The action of rennin on easein (pp. 10, 11).—This study was made for the purpose of determining whether the change from casein to paracasein is accompanied by cleavage of any of the elements contained in the casein molecule. The use of an excess of ammonia commented on by Harden and McCallum (see p. 607) was not found to result in the loss of phosphorus due to cleavage of the casein molecule. "The similarity between the composition of casein and paracasein, and the fact that casein has been shown to have a molecular weight of 8,888+ and a valency of 8, while paracasein has been shown to have a molecular weight of 4.444+ and a valency of 4, seems to be

evidence enough for concluding that the transformation of casein into paracasein is a process of hydrolytic splitting, one molecule of casein yielding two molecules of paracasein, and that this splitting of casein is not accompanied by a cleavage of any of the elements contained in the original casein molecule [E. S. R., 29, p. 805]."

Condition of casein and salts in milk, L. L. VAN SLYKE and A. W. BOSWORTH (New York State Sta. Tech. Bul. 39 (1914), pp. 3-17; Jour. Biol. Chem., 20 (1915), No. 2, pp. 135-152).—" Milk contains two general classes of compounds, those in true solution and those in suspension, or insoluble. These two portions can be separated for study by filtering the milk through a porous earthenware filter like the Pasteur-Chamberland filtering tube.

"Serum prepared from fresh milk is yellow with a faint greenish tinge and slight opalescence. The following constituents of milk are wholly in solution in the milk serum: Sugar, citric acid, potassium, sodium, and chlorin. The following are partly in solution and partly in suspension: Albumin, inorganic phosphates, calcium, magnesium. Albumin in fresh milk appears to be adsorbed to a considerable extent by casein and therefore only a part of it appears in the serum. In serum from sour milk and milk to which formaldehyde has been added, nearly all of the albumin appears in the serum.

"The insoluble portion of milk separated by filtration through Pasteur-Chamberland filtering tubes is grayish to greenish white in color, of a glistening, slime-like appearance, and of gelatinous consistency. When shaken with water it goes into suspension, forming a mixture having the opaque, white appearance of milk. Such a suspension is neutral to phenolphthalein. When purified, the insoluble portion consists of neutral cascinate (casein Ca₁) and neutral dicalcium phosphate (CaIIPO₄). The casein and dicalcium phosphate are not in combination, as shown by a study of 16 samples of milk from 13 individual cows, and also by a study of the deposit or 'separator slime' formed by whirling milk in a cream separator. By treating fresh milk with formaldehyde and whirling in a centrifugal machine under specified conditions, it is possible to effect a nearly complete separation of phosphates from casein.

"Both fresh milk and the scrum from fresh milk show a slight acid reaction to phenolphthalein, but are strongly alkaline to methyl orange, indicating that acidity is due, in part at least, to acid phosphates. In eight samples of fresh milk the acidity of the milk and of the milk scrum was determined after treatment with neutral potassium oxalate. The results show that the acidity of the whole milk is the same as that of the scrum, and that, therefore, the constituents of the scrum are responsible for the acidity of the milk. There is every reason to believe that the phosphates of the scrum cause the observed acidity."

In the study the Briggs apparatus for filtration (E. S. R., 14, p. 127) was employed. See also notes by Schreiner and Failyer and by Rupp (E. S. R., 17, p. 831; 29, p. 109).

On the basis of the data presented, taken together with many other analytical data worked out by the authors, the following composition of milk is suggested: "Total solids, 12.901 per cent: Fat 3.90, milk-sugar 4.90, proteins combined with calcium 3.20, dicalcium phosphate (CaHPO₄) 0.175, calcium chlorid (CaCl₂) 0.119, monomagnesium phosphate (MgH₁P₂O₈) 0.103, sodium citrate (Na₂C₆H₅O₇) 0.222, potassium citrate (K₂Cl₆H₅O₇) 0.052, dipotassium phosphate (K₂HPO₄) 0.230." The amounts are based on milk of average composition.

On the action of coagulating enzyms on caseinogen, A. Harden and A. B. Macallum (*Biochem. Jour.*, 8 (1914), No. 1, pp. 90-99).—"The conversion of caseinogen—into casein by enzym action is accompanied by the cleavage of

nitrogen, phosphorus, and calcium. Rennin action produces no soluble nitrogen or phosphorus. Trypsin splits off both soluble nitrogen and phosphorus, while the Withania enzym also produces soluble nitrogen and phosphorus but in smaller absolute quantities. The cleavage products are specific for each enzym and it is to this difference of enzym action that the variation in behavior of the resulting casein is to be ascribed. The precipitation of calcium caseinate by soluble calcium salts is not due to any chemical combination with these. The caseinogen once exposed to enzym action and redispersed can not be rendered more precipitable by renewed enzym action. If the enzym be sufficiently concentrated, precipitates are obtained without the addition of calcium salts and the same thing occurs with more dilute enzym solutions when the temperature is raised above 45°."

The importance of using an appropriate method for preparing easein is pointed out. "In preparations for milk the use of sodium hydrate was avoided so as to escape the possibility of hydrolyzing the protein. Van Slyke and Bosworth have used ammonia in the final stages of their method [E. S. R., 29, p. 9], allowing it to remain in contact with the caseinogen overnight. Their preparations have a very low ash content and the phosphorus content is the lowest yet recorded. This is due possibly to removal of phosphorus by the action of the alkali."

Caseinogen and casein, A. Geake (Biochem, Jour., & (1914), No. 1, pp. 30–37).—The object of this investigation was to determine the difference, if any, between caseinogen (casein) and casein (paracasein) in elementary composition and in the Hausmann numbers.^a See also a note by Osborne and Harris (E. S. R., 15, p. 221).

A slight modification of the Carius method was used for the sulphur determination. The results obtained for sulphur were higher than those which have been previously obtained for caseinogen. "The sulphur contents of caseinogen and casein appear to be identical, but casein apparently contains more phosphorus than caseinogen. The difference is, however, not sufficient to warrant the supposition that the two proteins are chemically different."

The figures for the Hausmann numbers were also too low to establish any definite differences.

The detection of potassium with tartaric acid, L. W. WINKLER (Ztschr. Angew. Chem., 26 (1913), No. 29, Aufsatzteil, p. 208).—Potassium bitartrate has the property of forming hypersaturated solutions, so that the use of a solution of tartaric acid as a reagent for detecting potassium often fails. If, however, the tartaric acid is used in powdered form and the solution is not too dilute, the characteristic precipitate is quickly obtained. The procedure recommended is as follows:

To 10 cc. of an approximately 5 per cent neutral solution of the substance under examination is added 0.5 gm. of crystalline powdered acetate, then approximately 0.5 gm. of powdered tartaric acid, and the mixture is shaken thoroughly. If no potassium (or ammonium, rubidium, or cesium) is present the solution remains perfectly clear. If the solution contains 0.2 per cent or more of the potassium ion the reaction occurs only after one to two minutes. It is advisable to conduct a control test with a solution of sodium chlorid or distilled water. The reaction can be employed for potassium chlorid, bromid, iodid, nitrate, chlorate, sulphate, etc., and the organic compounds of potassium, with the exception of tartar emetic. With alum the reaction is less sensitive.

^a Hoppe-Seyler's Ztschr. Physiol. Chem., 27 (1899), No. 1-2, pp. 95-108; 29 (1900), No. 2, pp. 136-145.

Detecting potassium with tartaric acid, H. Reckleben (Ztschr. Angew. Chem., 26 (1913), No. 49, Aufsatzteit, pp. 375, 376).—In discussing the method proposed by Winkler (see above) it is pointed out that when the concentrations are not properly controlled the potassium hydrogen tartrate is dissolved or the tartaric acid remains undiscolved despite the fact that the potassium ion may be absent. The test also loses its force when the necessity exists for making a blind test, as proposed by Winkler, with distilled water or a sodium chlorid solution. For a number of years the following procedure has been used, especially for beginners in the laboratory:

To the solution, which should not be too dilute, is added a fairly concentrated solution of sodium bitartrate. If it is desired to employ tartaric acid it should be utilized as a solution of tartaric acid containing sodium acetate, and with the precaution that the latter is not employed in a large excess. If no precipitate results on gently rubbing the walls of the vessel with a glass rod, the glass rod with its adhering fluid is put on a watch glass holding a few drops of a 10 per cent solution of a potassium salt, and when crystallization has set in the glass rod with its adhering fluid is replaced in the solution to be tested.

The author believes this method is better than the one proposed by Winkler.

The micro-chemical detection and distribution of aluminum in the plant kingdom, E. Kratzmann (Silzber, K. Akad, Wiss. [Vienna], Math. Nature. Kl., 122 (1913), I, No. 2, pp. 311–336, figs. 6).—The methods for the micro-chemical detection of aluminum in plant tissues recorded in the literature were studied and Cs₂SO₄ was the only reagent found satisfactory for detecting it as Al₂(SO₄)₃.Cs₂SO₄. The sensitiveness was 0.3 microgram. A modification of the method was necessary, however, in order to be able to work more rapidly.

One hundred and thirty plants representing various families were examined for the presence of aluminum. The results indicate that aluminum is widely distributed in the plant kingdom and some plants might justly be termed "aluminum plants." Many cryptogams show a marked accumulation of alumina in the sporophylls, and the blossoms of angiosperms contain more aluminum than the other parts of the plant.

The clay bodies described by Radlkofer could be found only in a few varieties of symplocos. It has not been definitely settled, however, that these bodies consist of clay only, and they probably contain silica. When aluminum is present with silica it is hard to detect, even with the Thénard blue test.

Some plants possess a specific selective affinity for aluminum.

The determination of the lime requirements of the soil, H. B. HUTCHINSON and K. MacLennan (Chem. News. 110 (1914), No. 2854, pp. 61, 62).—The various methods heretofore proposed for determining the lime requirements of soils, including those of Loew and Jones, are critically discussed. Veitch's method (E. S. R., 14, p. 418) was found to give results closely corresponding to the actual but it is claimed to be a very tedious process and difficult of adoption on a large scale. "It appeared, therefore, that a closer Investigation of the action of certain carbonates on the soil might give a measure of prevailing acidity, and would possibly conform more closely to natural conditions than some of the compounds hitherto employed."

As preliminary work with sodium earbonate and bicarbonate gave unsatisfactory results, the use of calcium bicarbonate was proposed. The solution is prepared "by passing a current of carbon dioxid into a suspension of calcium carbonate in distilled water, or by means of a 'Sparklet' or refillable soda water syphon, where bulbs of compressed carbon dioxid are used. The latter method is the more convenient, and permits of the preparation of a saturated solution within quite a short time. A large excess of carbonate must be used

in order to provide an abundance of small particles which readily pass into solution; the contents of the syphon may be diluted with one-third its volume of distilled water before filtering, and this will result in the formation of a solution of approximately tiftieth-normal strength.

"For a determination of acidity, or lime requirement, 10 to 20 gm, of the soil is placed in a bottle of 500 to 1,000 cc, capacity together with 200 to 300 cc, of the approximately fiftieth-normal solution of calcium bienrhonate, and the air in the bottle is displaced by a current of carbon dioxil in order to insure against possible precipitation of the calcium carbonate during the period of determination. The bottle is then placed in a shaking machine for three hours, after which time it is opened, the liquid is filtered, and a portion of the filtrate equal to half of the original amount of bicarbonate solution is titrated against tenth-normal acid, using methyl orange as indicator. The difference between this final titration and that of the initial solution represents the amount of calcium carbonate absorbed, each cubic centimeter of tenth-normal acid being equal to 5 mg, calcium carbonate.

"This method has been tested on a number of different soils, the behavior of which has been ascertained bacteriologically and chemically in the laboratory. A few of these results are summarized, in which the production of ammonia and nitrates and plant growth in untreated and limed soils is given. . . .

"In addition to its value for practical agricultural work, the method will possibly be of use in various ecological problems, where the relations between plant and soil require more accurate determination."

Method of determining the lime requirement of soils, C. H. Jones (Amer. Fert., 39 (1913), No. 11, pp. 28, 29).— Take 5.6 gm. soil, add 0.5 gm. calcium acetate (tested reagent), place in a 3-in, perfar, and mix with pestle. Add sufficient water (room temperature) to make a fairly stiff paste. Pestle for 20 seconds, add 30 cc. water, and continue mixing for 30 seconds. Wash into a 200-cc. flask, and keep bulk down to about 160 cc. Let stand, with occasional shaking, for 15 minutes. Make up to bulk of 200 cc., mix, and filter through a dry filter. Discard first 10 to 15 cc., which may be cloudy. Thrate 100 cc. of the clear filtrate, using phenolphthalein as an indicator with decinormal NaOH. This reading multiplied by 2 gives the cubic centimeters of decinormal alkali required to neutralize the acetic acid in 200 cc. of the solution. This figure times the factor 1.8 times 1.000 equals the pounds of lime (CaO) required per 2.000.009 lbs, of soil." The calculation may be shortened by multiplying the number of cubic centimeters of decinormal sodium hydroxid used by 3.000.

"The factor 1.8 is a tentative one only, it having been secured on a relatively small number of samples representing Rhode Island. Massachusetts, Vermont, and New Jersey soils. The method is extremely rapid, one man easily making 50 determinations in a day."

See also a previous note, Loew (E. S. R., 29, p. 815).

A new method for the determination of soil acidity, E. Tauog (Science, n. ser., 40 (1914), No. 1024, pp. 246-248).—One of the most serious drawbacks in the study of soil acidity is the lack of a suitable qualitative and quantitative method for its determination. While the littuus paper test when performed properly is a fairly satisfactory qualitative test its reaction with carbonic acid is confusing. With the view of securing a more reliable method the zinc sulphid test was devised, which depends upon the evolution of hydrogen sulphid when acid soils are boiled with zinc sulphid and water.

"Ten gm. of soil is placed in a 300 cc. Erlenmeyer flask and to this is added 1 gm. calcium chlorid, 0.1 gm. of zinc sulphid, and 100 cc. water. This is thoroughly shaken and then heated over a flame. After the contents have boiled one

minute, a strip of moistened lead acetate paper is placed over the month of the flask and the boiling continued two minutes more, when the paper is removed. If the soil is acid the paper will be darkened on the underside in proportion to the degree of acidity. If it is nonacid, no darkening will occur if the test has been performed as just outlined."

Calcium chlorid, which is added for the purpose of making the test much more sensitive, reacts with the comparatively insoluble soil acids and forms a small amount of hydrochloric acid which readily liberates the hydrogen sulphid from the zine sulphid. The test is said to detect much smaller amounts of soil acids than the litmus paper test. "The test has been applied to a considerable number of soils and also other materials of known reaction and as yet not a single objection to the test has arisen. As a quantitative method, an effort is being made to measure the degree of acidity by titrating with standard iodin solution the hydrogen sulphid which a soil will liberate. Whether this will work with all soils has as yet not been determined. By using this test for the end point in the Veitch lime water method for acidity or lime requirements, the present Veitch method is considerably shortened and made far more accurate."

Inasmuch as the test can be made approximately quantitative and still require only very simple apparatus and very little time (40 to 15 minutes), it makes a valuable field procedure. "The principle of this quantitative method depends upon the fact that for any particular class of soils the degree of acidity is closely proportional to the intensity of color produced on the paper when the test is conducted as previously outlined. The color on the test paper needs only to be compared to a standard color scale and from an accompanying table the degree of acidity or lime requirements is read off directly. This standard color scale is now being prepared and checked up with standard soil acids made by new methods."

A shaker for the mechanical analysis of soil, F. Ward (Jour. Indus. and Engin. Chem., 6 (1914), No. 2, pp. 147, 148, fig. 1).—A description of a homemade device.

"The writer believes that his method is better than the one used by the Bureau of Soils in two respects. In the first place the machine is simple, and inexpensive. A greater advantage is the saving of time. Clean separations can be effected in three hours, and in some cases two hours; this is a saving of at least four hours over the Bureau method. If the quantity of the water used in the bottles is reduced one-half, a clean separation results in much less than three hours, but there is a tendency for the grains to suffer some abrasion."

A shaker for the mechanical analysis of soils, C. C. Fletcher (Jour. Indus. and Engin. Chem., 6 (1914), No. 6, pp. 517, 518).—It is pointed out that although the machine mentioned in the abstract above is simple and inexpensive it carries only 16 bottles while that of the Bureau of Soils holds 48. It must also be run at a fixed speed to be efficient. The length of time required by the Bureau of Soils apparatus is not so great as stated, since a majority of soils, especially sandy soils, do not need seven hours' shaking. "The length of time of shaking does not result in any loss of time to the operator, as the analyst merely keeps 48 soils shaking on the machine all the time and can not complete the analyses rapidly enough with a force of three men to keep the machine cleared of samples ready for analysis. If more samples should be required, all that is necessary is to run the machine during the night, and thus the capacity of the machine would be doubled."

New investigations on the determination of citric acid-soluble phosphoric acid in Thomas slag powder, M. Popp (Chem. Ztg., 37 (1913), No. 109, pp. 1085-1087, fig. 1).—In this article the Popp method (E. S. R., 30, p. 809) is

described in full, and the results obtained with the method and other methods and slags of widely varying composition are given. The figures given by the Popp method compared well with those by the other methods.

Some work conducted at other experiment stations with the new iron citrate method and other methods (old iron citrate, hydrochloric acid, Naumann, and von Lorenz methods) is also reported. The results in general confirmed the author's conclusions in regard to injurious silicic acid. The new iron citrate method, when compared with the Naumann and hydrochloric acid methods, seemed to give the best result. The von Lorenz method on the average (100 analyses) gave 0.28 per cent less phosphoric acid than the Naumann method, and 0.25 per cent less than the hydrochloric acid method.

A field method for determining dissolved oxygen in water, J. Miller (Jour. 80c. Chem. Indus., 33 (1914), No. 4, pp. 185, 186).—The method adopted is as follows:

"To 50 cc, of the water contained in a 100 cc. Nessler cylinder is added 5 cc. of alkaline tartrate such as is used for Febling's solution and one drop of phenosafranin solution (1 in 2,000 of water), then from a 10 cc. graduated pipette a solution of ferrous sulphate (0,22 gm. of pure FeSO₄ and 1 cc. of concentrated sulphuric acid in 100 cc.) is run in just below the surface of the liquid, stirring gently with the pipette until the color is discharged, looking through the cylinder horizontally. The ferrous sulphate is added 1 cc. at a time until the color begins to fade, then in additions of 0.5 cc. to the end. There is a slight coloration at the surface of the liquid, but if the stirring is not too vigorous this does not interfere. The outlet hole of the pipette should not be more than 1 mm. in diameter to minimize diffusion.

"The pipette reading gives the cubic centimeters of oxygen per liter. Theoretically 1 cc. ferrous sulphate of above strength does not equal 1 cc. oxygen per liter working on 50 cc. of sample (0.25 per cent FeSO₄ is theoretical strength), but under the conditions stated I have found that the above strength gives correct results.

"Each experimenter should standardize his ferrous sulphate against water of known oxygen content, say distilled water shaken with air until saturated, taking the temperature and referring to Roscoe and Lunt's table (Sutton's Volumetric Analysis, page 260) for the amount of dissolved oxygen present."

The results obtained compared well with those given by the Winkler method. The detection of extracted paprika, G. Heuser and C. Hassler (Ztschr. Untersuch. Nahr. u. Genussmil., 27 (1914), No. 1-3, pp. 201-209).—For determining whether paprika has been extracted the iodin number is considered satisfactory on account of the ease and rapidity with which it can be determined. The ether extract is, however, a better constant for judging paprika than the alcohol extract. For simplifying and shortening the time necessary for extraction a modification of the Röse-Gottlieb method is suggested.

A field test for lime-sulphur dipping baths, R. M. Chapin (U. S. Dept. Agr. Bul. 163 (1915), pp. 7, fig. 1).—The object of this paper is to describe a portable testing outfit devised and employed by the Bureau of Animal Industry for determining the strength of lime-sulphur dipping baths used in the official dipping under regulations now in force. "This method, however, is intended only for field use; it can not replace in the laboratory the more accurate methods of analysis approved by the Association of Official Agricultural Chemists. . . .

"The test here described employs the well-known reaction between soluble sulphids and iodin in neutral solution, whereby sulphur is precipitated and a metallic iodid is formed. It therefore directly estimates, not sulphur, but the

metal—in this case calcium—combined with sulphur in the form of sulphid or polysulphid, . . . Briefly, the method of test involves the addition of standard iodin solution to a measured quantity of bath until the resulting liquid no longer gives color with a dilute alkaline solution of sodium nitro-prussid, showing that calcium polysulphid has been entirely decomposed. The amount of iodin added to reach this point is then a measure of the amount of 'sulphid sulphur' in the bath."

The outfit used is illustrated and tables showing quantities of concentrated dip to be added to each 100 gal, of bath to restore it to the standard strength (1.5 to 2 per cent sulphid sulphur) are given.

About some seeds which have rarely been examined and their oils, A. Diedmens (Zlschr. Untersuch. Nahr. u. Genussmil., 27 (1914), No. 1-3, pp. 132-141).—This gives data in regard to the China orange, lemon, India butter free (Bassia butyracca), Stillingia, and Calotropis or akoon (C. giyantca).

Agricultural alcohol: Studies of its manufacture in Germany, E. Kremers (U. 8. Dept. Agr. Bul. 182 (1915), pp. 35).—These data collected in Germany deal with the topic under the following headings: History; the economic situation: mash-capacity taxes, 1820 and 1868; taxes on the finished products, 1887; tax refunds on industrial alcohol, 1879 and 1887; increase in technical applications of alcohol; distillation of tax of 1895, and bonus on industrial alcohol; increase in potato culture; cooperation in marketing; organization of the central association; success of the central association; voluntary regulation of production; the potato the principal source of alcohol; the distillery as a factor on the market; distilleries on the larger estates and domains; distilleries on small farms; cooperative distilleries; and a report of visits to agricultural distilleries at Dahlem, Dahlewitz, Dominium Neuguth-Heinzenburg, Treben, Weihenstephan, and Perlach.

Osage orange.—Its value as a commercial dyestuff, F. W. Kressmann (Jour. Indus. and Engin. Chem., 6 (1914), No. 6, pp. 462-464).—This is a study of the utilization of Osage orange mill waste. As a rule the trunk of an Osage orange tree is small in size, misshapen, and generally defective as a saw log, "and, although because of the valuable properties of the wood (for wagon felloes especially) closer utilization will scarcely be found in the use of any other wood, comparatively large amounts of waste are produced annually.

"Osage orange has long been used in Texas in a small way as a dyewood. The roots, bark, and wood are chipped and boiled with water and a more or less permanent yellow is obtained from the extract." As a result of the investigation it was found that the quality and quantity of the dyestuff present is almost identical with that of fustic.

"Osage orange may be employed as a dyewood in all cases where fustic wood is used at present. The yellows produced by direct dyeing or by aluminum and tin mordants are too fugitive to be of commercial value. But the orange-yellows, old gold, deep tan, olive, and chocolate shades obtained with chromium and iron dormants are equal to, if not better than, those obtained with fustic and are of sufficient fastness to be of commercial value.

"A domestic source of a yellow dyewood has been found that can advantageously replace a foreign material used at present. The mill waste alone from the present manufacture of osage orange amounts to over 25,000 tons annually; and if this waste could be set down in the East for \$10 or \$12 per ton it is believed that it could compete successfully with fustic, both from cost of production and quality of color produced on dyeing."

METEGROLOGY.

Monthly Weather Review (Mo. Weather Rev., 42 (1914), Nos. 9, pp. 519-559, pls. 8, figs. 8; 10, pp. 561-608, pls. 24, figs. 6).—In addition to notes on weather forecasts for September and October, 1914, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology, notes from the Weather Bureau library, the weather of these months, a condensed climatological summary, and climatological tables and charts, these numbers contain the following articles:

No. 9.—Solar Radiation Intensities at Mount Weather, Va., During July, August, and September, 1914, by H. H. Kimball; Notes on Observing the Zodiacal Light, by M. Hall; Shooting Stars Reveal a Higher Atmosphere; Influence of Terrestrial Rotation on the Condition of the Atmosphere and Ocean (illus.), by J. W. Sandström; Daily March of the Meteorological Elements in the Panama Canal Zone, by J. von Hann; The Function of the Atmosphere in [Wireless] Transmission (illus.), by J. Erskine-Murray; Rainfall after Battle, by H. M. Chittenden; The Hourly Frequency of Precipitation at New Orleans, La. (illus.), by E. D. Coberly; Forecast Distribution (illus.), by G. W. Smith; and Heavy Rainsform at Kansas City, Mo., by P. Connor.

No. 10.—Frost Protection (illus.), by W. J. Humphreys; Utilization of Frost Warnings in the Citrus Region near Los Angeles, Cal. (illus.), by F. A. Carpenter; Frost and Frost Prevention, by J. W. Garthwaite; Air Drainage in the Vicinity of the Corona District, Cal. (illus.), by F. A. Carpenter and J. W. Garthwaite; Frost Warnings and Orchard Heating in Ohio (illus.), by J. W. Smith; Air Drainage Explained, by C. F. Marvin; Protection Against Frost in Georgia, by C. F. von Herrmann; Protection from Frost in Utah, by A. H. Thiessen; Notes on Frost Protection in the Vicinity of Knoxville, Tenn., by J. F. Voorhees; Frost Forecasts and Protection in Oregon, Washington, and Idaho, by E. A. Beals; Frost and Frost Protection in Florida, by A. J. Mitchell; Frost Protection in Arizona, by R. B. Briggs; Frosts and Frost Protection in Texas, by M. Spragne; and Frost Protection by Irrigation in Southern Texas, by J. L. Cline.

Climatological data for the United States by sections (U. S. Dept. Agr., Weather Bur. Climat. Data, 1 (1914), Nos. 11, pp. 224, pls. 2, figs. 8; 12, pp. 236, pls. 2, figs. 7).—These numbers contain brief summaries and detailed tabular statements of climatological data for each State for November and December, 1914, respectively.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. Ostrander and R. E. McLain (Massachusetts Sta. Met. Buls. 313, 314 (1915), pp. 4 cach).—Summaries of observations at Amherst, Mass., on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during January and February, 1915, are presented. The data are briefly discussed in general notes on the weather of each month.

[Meteorological observations], D. A. SEELEY (Ann. Rpt. Sec. Bd. Agr. Mich., 53 (1914), pp. 185-198).—Daily and monthly summaries of temperature (maximum, minimum, and mean), precipitation, cloudiness, and sunshine, and monthly summaries of pressure (maximum, minimum, and mean), wind movement, and miscellaneous phenomena (frost, hail, thunderstorms, fog, auroras, and halos) are given for the year ended June 30, 1914.

Meteorological records for 1913 (New York State Sta. Rpt. 1913, pp. 789-801).—Tables are given showing tridaily readings at Geneva, N. Y., of standard air thermometers for each month of the year; daily readings of maximum and minimum thermometers at 5 p. m. for each month of the year; a monthly sum-

mary of maximum, minimum, and standard thermometer readings; monthly and yearly maximum and minimum temperatures from 1883 to 1913, inclusive; average monthly and yearly temperatures since 1882; and rainfall by months since 1882.

Response to rainfall in India, L. O. Packaro (Bul. Amer. Geogr. Soc., 47 (1915), No. 2, pp. 81-99, figs. 3).—This article discusses the factors controlling distribution and variation of rainfall in India and its relation to irrigation, crop production, and man's welfare. The relation to rainfall variation of topography, extra-tropical cyclones, summer monsoons with their accompanying cyclones, and proximity to the sea with long-continued sea winds is briefly explained.

Among crops which require heavy rainfall or irrigation are named rice, jute, ten, and coffee. Sugar cane is also grown in the wet areas. "Jute, ten, and coffee differ from sugar and rice in that their areas are not extended by irrigation but are limited to those regions in which water is supplied wholly by rainfall, . . . Crops requiring less water are wheat, millets, pulses, and cotton. Wheat and cotton are injured by heavy rains, especially during the later stages of growth. For this reason cotton, although a summer crop, is limited to those provinces having a comparatively light rainfall, as in parts of northern India and in the northern and central parts of peninsular India. . . .

"Two crops a year are raised in many parts of India, although in many cases the poor soils, combined with primitive methods of cultivation, do not permit two crops to be raised upon the same land in a given year." However, "in most parts of the country the rainfall, in favorable seasons, is well adapted for two crops per year. . . .

"For the reason that rainfall is always scanty in certain parts of India, and that nearly all parts are subject to seasons of light rain, or of unsatisfactory distribution of rainfall, irrigation systems have been developed throughout the country. The regions receiving heavy rainfall, and consequently those in which chances of failure are remote, are Bengal and Assam and the strip of territory west of the Western Ghats."

Irrigation is secured by means of canals and wells, the latter supplying water for only small areas (1 to 20 acres).

Nitrogen compounds in rain and snow, F. T. Shutt (*Proc. and Trans. Roy. Soc. Canada*, 3, ser., 8 (1914), Sect. 111, pp. 83-87).—In continuation of previous reports (E. S. R., 32, p. 419), this article records the results of studies on this subject during the seven years ended February 28, 1914.

The average amount of nitrogen brought down by the precipitation during this period is shown to have been 6.182 lbs. per acre. Approximately 70 per cent of this was in the form of free and organic ammonia and 30 per cent nitrates. Approximately two-thirds of the total precipitation was rain and this supplied very nearly 85 per cent of the nitrogen. The observations show that the rain is decidedly and invariably richer than snow in nitrogen compounds.

It was observed that the prevalence of bush or forest fires increased the ammonia content of the precipitation to a marked extent. A light rainfall after a period of hot, dry weather was especially rich in nitrogen compounds, Rain during thunderstorms was always found to be rich in nitrogen, but this is attributed more to an increased amount of dust in the air than to nitrates produced by electric discharges.

In these studies every precipitation of rain or snow that was sufficient for analysis was chemically examined, it having been observed that results from composite samples representing the rain of a week or a month were not reliable. "The collection of the samples of rain was made on a leaden tray or basin,

placed about 20 ft. from the ground, which for some distance around is lawn and shrubbery. It is approximately 60 by 30 in. The water as it falls is conducted from the boftom of the basin by means of a glass tube into a glass jar, from which the sample for analysis is taken at the end of each rainfall."

Nitrogen and chlorin in rain and snow, W. K. Knox (Chem. News, 111 (1915), No. 2880, pp. 61, 62).—In continuation of previous studies by Wiesner (E. S. R., 30, p. 815) the author reports determinations of the nitrogen and chlorin content of 36 samples of rain and 7 of snow collected at Mount Vernon, Iowa, from October 4, 1943, to June 12, 1944. The snowfall during the period amounted to 11.5 in., equivalent to 0.95 in. of rain. The rainfall was 17.75 in.

It is estimated from the determinations that the total precipitation during the period named carried down to the soil 36.85 lbs. of chlorin per acre, 1.54 lbs. of nitrates, 0.01 lb. of nitrite, 3.69 lbs. of free animonia, 2.79 lbs. of albuminoid ammonia, and 0.13 lb. of sulphate.

SOILS-FERTILIZERS.

Soil survey of Goodhue County, Minnesota, W. G. Smith et al. (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1913, pp. 34, fig. 1, map 1).—This survey, issued February 3, 1915, deads with an area of 490,880 acres in southeastern Minnesota, consisting of rolling to hilly upland which drains eastward into the Mississippi River. The soils of the area consist mainly of dark brown to black silt loams with relatively small areas of stony gravelly soils, and are grouped naturally into upland, high river terraces, and overflow bottom land. Twenty-five soil types of ten series and two miscellaneous types are mapped. The Knox silt loam, covering 43 per cent of the area, is the most important and extensive upland type, the Waukesha silty clay loam is the most extensive river terrace type, and the Wabash soils are the most important of the bottom land types. It is stated that an excessive acreage in small grain and too little in clover has materially reduced the producing power of the naturally strong soils of the county and that a reorganized cropping practice is necessary.

The soils of Pennsylvania, C. F. Shaw (*Pennsylvania Sta. Bul. 132* (1914), pp. 209-242, fig. 1).—This bulletin summarizes the results of a reconnoissance survey of the soils of Pennsylvania made by the Bureau of Soils of this Department in cooperation with the Pennsylvania State College.

The State is naturally divided into three physiographic sections. The first lies east and south of Blue Mountain and has a generally rolling to hilly topography. The second lies between Blue Mountain and the Allegheny escarpment and consists of a succession of mountain ridges and valleys. The third lies west and north of the Allegheny escarpment and has a topography varying from rolling to hilly and mountainous.

Seventy-four per cent of the soils of the State are residual in origin, 22 per cent are glacial, and 4 per cent are alluvial and lacustrine. The soils are classed in seven provinces and forty-seven series. The Dekalb series is the most extensive, covering 43.5 per cent of the State, and the Volusia series is second, covering 19.4 per cent of the area. Each soil series is briefly discussed with reference to extent, distribution, general characteristics, and crop adaptabilities.

Soil survey of Orangeburg County, South Carolina, J. H. Agee et al. (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1913, pp. 39, fig. 4, map 1).—This survey, issued February 16, 1915, deals with an area of 702,720 acres in south-central South Carolina, the topography of which ranges from

level to gently rolling. Most of the lands are in the Coastal Plains province, a small part in River Hood Plain province, and there is a gradation from well-drained rolling lands to poorly drained swampy flats. The southern and south-eastern parts of the county are very poorly drained. The soils of the county are grouped according to origin as sedimentary, alluvial, and colluvial, the first greatly predominating. Twenty-seven types comprising eleven series and two miscellaneous types are mapped and described, of which the Norfolk series is the most extensive (over half of the total area). The Orangeburg sandy loam covering about 4 per cent of the total area "is one of the strongest soils in the county and most of it is under cultivation." About half the area of the county is under cultivation, cotton being the most important crop. Commercial fertilizers are used extensively but rotation of crops is not generally practiced although followed on many farms. "The mellow character of the soils, coupled with the favorable surface features, invites the use of all kinds of labor-saving machinery."

Soil survey of Washington County, Texas, A. II. MEYER ET AL. (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1913, pp. 31, fig. 1, map 1).— This survey, issued January 26, 1915, deals with an area of 392,320 acres in southeastern Texas, the topography of which varies from level to rolling. Drainage is said to be generally good. The soils of the area are of residual and alluvial origin and range from a heavy waxy clay through a loam and sandy loam to a loamy sand and fine sand. Five series, comprising eleven types, are mapped. The Houston types cover about two-thirds of the county and of these the black clay is the most extensive. It is stated that, although the agriculture of the county is generally prosperous, little attention is given to the adaptation of soils to crops and no system of crop rotation is followed.

Better crop adaptations for the different types of soil are suggested. Farm manure is generally used with very beneficial results. "There is a general need for more thorough tillage, deeper plowing, and the conservation of soil moisture."

Soil survey of Boone County, West Virginia, W. J. LATIMER (U. S. Dept. Agr., Advance Sheets Field Operations Bur. Soils, 1913, pp. 26, fig. 1, map 1).— This survey, made in cooperation with the West Virginia Geological Survey, was issued February 10, 1915. It deals with an area of 323.840 acres in southwestern West Virginia, the topography of which is rough and broken. Only about 25 per cent of the area is cleared. The northeastern part is drained by the Coal River and the remainder mainly by the Little Coal River and its tributaries. The soils of the county are grouped as upland or residual soils, terrace or second bottom soils, and first bottom or overflow land. Eleven soil types, comprising four series, and two miscellaneous types are mapped, of which the Dekalb stony silt loam is the most extensive, covering 85.2 per cent of the county. The principal crops grown are corn, oats, hay, potatoes, and vegetables. Very little commercial fertilizer is used and no general system of crop rotation is practiced in the county.

The properties of soil grains and the plasticity of soils, A. Atterberg (Kolloidchem. Beihefte, 6 (1914), No. 2-3, pp. 55-89, figs. 3; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 623, I, p. 1120).—The author takes the position that mechanical analysis alone is not adequate for distinguishing the properties of different classes of soils. It is deemed also necessary for this purpose to have knowledge of the physical properties (hygroscopicity, pore space, capillarity, water capacity, relation to root hairs, flocculation, Brownian movement, etc.) of the different grades of soil particles. Moreover, many soils are rich in ultramicroscopic bodies and the properties of such soils will be determined largely by the nature and properties of the colloid bodies present.

The author proposes and explains a system of classifying such soils by their varying degrees of plasticity. For this purpose the ordinarily accepted classifications of soil particles do not go far enough into the microscopic and ultramicroscopic particles, but he approves of the proposed international classification (E. S. R., 31, p. 417). Ordinarily it is necessary for a rational classification to take account only of particles 2 mm., 0.2 mm., 0.02 mm., and 0.002 mm, and less in diameter. The author's apparatus and methods for mechanical analysis of soils, especially for the separation of the very fine microscopic and ultramicroscopic particles, are described.

Soils containing more than 50 per cent of coarse sand (2 to 0.02 nm.) are considered dry sandy soils fit only for forestry. Soils containing more than 50 per cent of fine sand (6.2 to 0.02 nm.) or silt (6.02 to 0.002 mm.) may be classed as loamy clay, normal loam, or loamy sand. Soils containing more than 50 per cent of colloid particles (0.602 nm. or less) are very heavy, highly plastic clay soils. The importance and value of determining the degree of plasticity in the latter class of soils are especially emphasized, and simple methods of determining the limits of (1) finidity, (2) "rolling out," and (3) sticky plasticity are described.

Two natural classes of clay soils based on such determinations are distinguished, (1) highly plastic (sticky) clays containing more than 50 per cent of colloid particles, and (2) less plastic soils containing more than 50 per cent of time sand or silt. The determination of plasticity of clays is preferred to mechanical analysis because it is very simple and much more rapid. Further study of the colloid substances which determine the plasticity of soils is in progress.

The course of denitrification in soils of different water content, O. Lemmermann and J. L. Wichers (Centbl. Bakt. [ctc.], 2. Abt., 41 (1914), No. 18-23, pp. 608-625, fig. 1).—The authors review work of others bearing on the subject and report comparative studies of three soils of different water-holding capacities with reference to the intensity of the denitrification process. With the same relative water content with reference to the total water capacity entirely different results as regards nitrate reduction were obtained with the three soils. The most nitrates were destroyed in all three soils when the water content corresponded to the total water capacity. The formation of elementary nitrogen decreased with decreasing water content, but was not always the least with the least water content. This is thought to be due to the influence of other bacteriological processes on the denitrification process.

The chemistry of soils: Evolution of purins, G. Chardet (Rev. Gén. Chim., 17 (1914), No. 10, pp. 154, 155; abs. in Chem. Zentbl., 1914, II, No. 10, p. 655).— In continuation of a previous article (E. S. R., 31, p. 515) the author briefly discusses certain theoretical considerations involved in the breaking down of nucleo-proteids with simultaneous formation of purin bodies. It is concluded that the purin bases occur in the soils either as nucleic acids derived from vegetable alkaloids or formed from the nucleo-proteids of dead micro-organisms. They occur in very small amounts in soils and it is not likely that they exert any considerable influence on plant growth.

The effect of deciduous and evergreen trees on the soil and its vegetation, A. Koch (*Centbl. Bakt.* [*ctc.*], 2. *Abt.*, 41 (1914). No. 18-23, pp. 545-572, pls. 4).—The author reviews the work of others bearing on the subject, and reports studies of the humus of pine and beech forest soils and of the volatile oils and other products of conifers with reference to the germination of seeds, the growth of plants, and the life and activity of yeasts and soil and other bacteria.

Buckwheat and cabbage plants and beech and pine seedlings grew much better in the beech humus than in the pine humus. Both kinds of humus were found to be better stocked with plant food than a productive field soil. The pine humas reacted weakly acid and liming slightly improved growing conditions.

Turpentine and carvene when applied to a loam soil retarded the germination of corn, but this effect was apparent only during germination. No effect was observed with these products when used in the presence of tannin. Silver pine-needle oil slightly retarded germination and chlorophyll formation. The addition of ground pine needles to soil, while apparently not affecting germination, retarded the growth of the plant, which effect the author attributes to the favorable influence of the pine needle cellulose on the activity of denitrifying bacteria rather than to poisonous secretions. Formic acid strongly retarded germination. Carvene and turpentine were both temporarily but increasingly toxic to corn plants. The vapors of a number of the volatile conifer products were found to be more or less toxic to Impaticus suttanii, rape, and cresses.

The volatile products also retarded the formation and activity of soil ferments, were more or less toxic to soil and milk bacteria, and, with one exception, more or less retarded the formation of nitrates from the ammonia of urine.

The oxidation of ammonium sulphate in beech humus was marked, while in pine humus it was either small or negative. Comparative studies of the effects of decomposing beech leaves and pine needles on the reduction of sodium nitrate showed them to be about equally active. The volatile products had little retarding influence on the reduction of sodium nitrate but markedly retarded the bacterial decomposition of cellulose.

It is concluded from these studies that the most of the different coniferous products tested are toxic to higher plants, yeast, and bacteria, and that the humus of pine forests, in contrast to the humus of beech forests, has a generally unfavorable effect on plant growth.

A list of references to literature bearing on the subject is appended.

Field test with toxic soil constituent: Vanillin, J. J. SKINNER (U. S. Dept. Agr. Bul. 164 (1915), pp. 9, pls. 4).—Pot and field experiments on the effect of vanillin, a soil constituent (E. S. R., 30, p. 610), upon plant growth are reported.

In pot experiments using a loam soil clover was stunted in growth and its green weight reduced 53 per cent when 100 parts per million of vanillin was present. In pot experiments with wheat using an infertile sand, an infertile sandy loam, and a fertile loam vanillin in concentrations varying from 100 to 500 parts per million was harmful in the two infertile soils and had no effect in the fertile soil. The negative effect in the fertile soil is attributed to its stronger oxidizing power.

In field experiments on an acid silty clay loam with cowpeas, string beans, and garden peas the harmful effect of the vanillin when added at the rate of 285 lbs. per acre was noticeable from the beginning and throughout the experiments. Six months after application this soil still contained vanillin, and when used in pot experiments was harmful to wheat, cowpeas, string beans, and garden peas.

The number and growth of protozoa in soil, J. M. Sherman (Centbl. Bakt. [etc.], 2. Abt., 41 (1914), No. 18-23, pp. 625-630; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases, 5 (1914), No. 9, pp. 1165, 1166).—Studies, using the dilution method, on sixteen soils representing various types under various treatments as to cultivation indicated that the normal fertile soil has a protozoa content approximating 10.000 per gram. "The flagellates constitute the greater portion of the protozoan fauna of the soil, and not the ciliates nor amæbæ. Colpoda cucullus appears to be the most widely distributed ciliate in soil, and may occasionally be found in numbers approximating 1,000

per gram. The amœbæ do not ordinarily occur in numbers nearly as great as do the flagellates. Certain forms of the soil protozoa are active under normal, and even subnormal, conditions of moisture. The active protozoan inhabitants of most soils are probably restricted to the flagellates. *C. cucutlus* is probably active whenever the moisture content is much above normal, but does not appear to be so ordinarily."

Methods of soil sterilization for plant beds and greenhouses, A. D. Selby and J. G. Humbert (Ohio Sta. Circ. 151 (1915), pp. 65-74, figs. 2).—This circular describes the perforated pipe and inverted pan methods of steam sterilization and the formalin method of sterilization for plant beds and greenhouse soils, gives cost data for the different methods, and notes reports on practice in sterilizing soils. The estimate of costs of operation by the different methods is \$15.40, \$12.20, and \$21, respectively, to treat a house 3.000 sq. ft. in area.

As regards soil sterilization, it is stated that "in general, a sandy soil will require less time to be thoroughly heated to the desired depth than will a silt-loam soil or one of heavier clay. . . . A dry soil, and particularly one containing a high percentage of humus, will be very apt to suffer some injury, especially in that portion next to the steam pipes. Light soils, and those rich in humus, would better be steam treated with the pan method. . . . In practice soil should be wetted to the extent of a little less than good growing conditions when steamed either by pipes or by the pan method; this condition will generally be found satisfactory in using the formaldehyde drench. . . Great caution must be observed that a recently steamed soil is not overwatered, thus giving it the water-logged structure which prohibits or greatly retards growth of plants. . . . Beds treated with formaldehye (3 pints to 50 gal, of water or stronger) should be stirred every few days to rid the soil of fumes poisonous to young plants, and such beds should not be seeded or planted for a period of ten days after the drench is applied."

The present position of the science of manuring in Germany, M. HOFFMANN (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 8, pp. 976-984).—It is stated that while "the weightiest problem of the science of manuring, namely, how to find out, rapidly and surely, the manurial requirements of a given piece of land before a crop is put into it," has not yet been solved, considerable progress in this direction has been made possible by the work of König on the treatment of soil by steam under pressure, by Mitscherlich on the use of solutions of carbon dioxid, and by Gerlach on the use of 2 per cent citric acid as means of determining the available plant food of soil, and by the work of Wagner and Pfeiffer on plant analysis. It is stated that Wagner's conclusion that meadows, the air-dried hay of which contains less than 2 per cent of potash, 0.7 per cent of phosphoric acid, and 1 per cent of lime, need applications of these substances has been repeatedly confirmed, and attempts are being made to establish similar standards for cereals. Generally, however, field and pot experiments are still to be considered the best means of determining the fertilizer requirements of soils and crops.

In default of such experiments "soil statics," or keeping account of income and outgo of soil fertility, is recommended as a useful guide in fertilizing. Another guide is furnished by the fact that in normal plants, with the possible exception of Leguminosæ, the relative proportions of plant food constituents are approximately nitrogen 100, phosphoric acid 50, potash, 150, and lime 80. "The farmer who reckons out his stock of the principal plant foods per acre for each piece of arable land on the basis of an up-to-date and complete soil analysis, and from this subtracts the quantity of plant foods contained in the forthcoming crop at harvest (allowing about 1 per cent for wastage) on the

above ratio, will be able to measure approximately, before the annual crop sowing, the quantities of manure which he must still apply to his land. In doing this, however, he must take into consideration the average coefficients of utilization of the said plant foods and all the other factors which influence the productive capacity of the soil."

It is recognized that while these suggestions may be extremely helpful, "there exists at present no method at once rapid and entirely free from objection, of determining the manurial requirements—not the plant food requirements—of a soil, and there is not likely to be one until the biological and colloido-chemical actions taking place in the soil have been more clearly defined."

In dealing with questions of fertilizing it is useful to keep in mind the law of minimum as defined by Liebig, or the law of physiological relations as defined by Mazé and Mitscherlich, and here it must also be borne in mind "that certain factors formerly regarded as being present in excess, for example, carbonic acid, are now suspected of being present only in the minimum quantity." Account must be taken of the variation in assimilating power of different plants, as explained in Strakosch's "law of the variation of work done by plants" and in his idea of assimilative effect (E. S. R., 30, p. 332).

As shown by Schulze and von Seelhorst, with the roots and stubble or even the whole plant of leguminous crops turned under, the soil can not be depended upon to preduce maximum crops. Only about 30 per cent of the nitrogen of green manures has been shown by von Seelhorst (E. S. R., 30, p. 24) to be utilized by a three-course rotation.

To get the best results solid and liquid manures should be stored separately. "The liquid manure should be kept from contact with the air in a tank with a lid, and should also be covered with a layer of petroleum or oil,"

Experiments which have been carried on for 70 years on a farm at Wingendorf near Freiberg, Saxony, seem to show that complete replacement of farm manures by commercial fertilizers "can not be continued through several decades without fundamentally impairing the yield, except on good soils containing plenty of humus, and even then, only when the remains of the roots and stubble are allowed to accumulate for the enrichment of the soil." However, it is shown that the great increase in the systematic and scientific use of fertilizers in Germany has been accompanied by a corresponding increase in crop yields.

In the author's opinion "the quintessence of human art in agriculture lies . . . in the correct application of fertilizers to well prepared soil, and in sowing productive varieties."

Some facts about commercial fertilizers in New York State, L. L. Van Slyke (New York State Sta. Bul. 392 (1914), pp. 585-625).—This bulletin (1) calls attention to differences in cost of plant food in commercial fertilizers sold in New York, with suggestions as to the more economical purchase of such plant food, (2) discusses the relation of guarantied to actual composition, and (3) shows that the present state fertilizer law "needs amendment in order to limit more carefully the amounts of deficiencies that are absolutely exempt."

It is shown among other things that "the tendency among farmers at the present time appears to be in the direction of purchasing more high-grade mixtures, [but that] in complete fertilizers as well as in other mixtures and unmixed materials, the variation in selling price is often wholly out of proportion to the amount of plant food present. . . . Plant foods can be purchased generally in unmixed materials at less cost than in mixtures."

The analyses of fertilizers sold in the State in 1914 show that "in the case of each constituent of complete fertilizers, the number of samples showing results

above the guarantied statement of composition is much larger than the number below. . . . In the case of fertilizer materials and mixtures other than complete fertilizers, the average percentage found is above that guarantied in all cases excepting fish scrap and calcium (time) carbonate." However, "the present law permits absolute exemption of deficiencies of plant food amounting in some cases to a value of \$5 or more per ton [and] in the case of high-grade fertilizers and especially of fertilizing materials . . . offers an opportunity for cheating farmers with impunity."

Fertilizer facts for farmers, F. H. HALL (New York State Sta. Bul. 392, popular ed. (1914), pp. 8, fig. 1).—A popular edition of the above.

The action of sulphate of ammonia and superphosphate of ammonia in calcareous soils, J. Wlodeck (Abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Ptant Discases, 5 (1914), No. 8, pp. 1004, 1005).—In field experiments with cereals on calcareous and sandy soils to determine losses of nitrogen from ammonium sulphate and to test the behavior of superphosphate of ammonia in calcareous soils, it was found that while the superphosphate was about equally effective on the two soils, the sulphate gave much lower results on the calcareous soil than on the sandy soil. The conclusion is drawn that the unfavorable result with the sulphate on the calcareous soil was due to volatilization of ammonia, and that losses of as much as 20 per cent of the ammonia may result from this cause whereas with superphosphate of ammonia such losses can be avoided or considerably reduced.

The eyanamid works at Niagara Falls (Engin News, 73 (1915), No. 1, pp. 16-21, flys. 5).—The present status of the synthetic nitrogen industry, with particular reference to the cyanamid process, is reviewed, and the works at Niagara Falls, Ontario, is described. It is stated that the present annual production of cyanamid is as follows: Odda, Norway, 72,000 metric tons; Alby, Sweden, 16,000; Piano d'Orta, Italy, 6,000; Terni, Italy, 25,000; San Marcel, Italy, 3,000; Martigny, Switzerland, 12,000; Notre Dame de Briancon, France, 7,500; Trostberg, Bavaria, 25,000; Gross-Kayne, Germany, 6,000; Knapsack, Germany, 20,000; Selenico, Dalmatia, 6,000; Dugriat, near Almissa, 15,000; Kagami, near Kumamoto, Japan, 16,000; and Lonza, Switzerland, 15,000 metric tons; and Niagara Falls, Ontario, 64,000 long tons. Practically the entire American output of cyanamid is used in the preparation of mixed fertilizers.

The Niagara Falls factory occupies a plat of 40 acres, covers 12 acres of floor space, represents an investment of \$3,000,000, normally employs continuously day and night about 750 men and 30,000 horsepower of electrical energy, and produces cyanamid of a sales value of approximately \$2,750,000 a year.

Comparison of silicates and carbonates as sources of lime and magnesia for plants, W. H. Macinthe and L. G. Willis (Jour. Indus. and Engin. Chem., 6 (1914), No. 12, pp. 1005–1008, figs. 2).—The authors review previous work indicating that calcium and magnesium more commonly occur in soils as silicates than as carbonates and report tests of the carbonates and silicates in pot experiments with clover. The soil had a lime requirement of about 1 ton per acre surface foot. The substances tested were used in amounts furnishing the equivalent of 16,070 lbs. per acre in excess of this requirement.

The results indicated that "calcium and magnesium mineral silicates, wollastonite, and serpentine were very beneficial when applied either singly or jointly.... Calcium silicate is decidedly superior to calcium carbonate, both in its effect upon plant growth and as a form tending to conserve lime in soils."

The comparative effect on different kinds of plants of liming an acid soil, B. L. Hartwell and S. C. Damon (Rhode Island Sta. Bul. 160 (1914), pp. 407-446, pls. 4).—This bulletin summarizes the results secured during 22 years (1903)

to 1914) on four plats equally and liberally fertilized as regards nitrogen, phosphorus, and potassium, two of the plats receiving their nitrogen in ammonium sulphate and the other two in sodium nitrate, and one of each pair receiving slaked lime from time to time.

The results of the first eight years' experiments of this series have been previously reported (E. S. R., 15, p. 672).

During the 22 years the plats received average annual applications of 44.5 lbs, per acre of nitrogen in ammonlum sulphate or sodium nitrate, 90 lbs, of phosphoric acid in dissolved boneblack or acid phosphate, and 114 lbs, of potash in muriate of potash. The total application of lime during the period was 6,350 lbs,; 4,750 lbs, in two applications in 1893 and 1894, and 800 lbs, in 1902 and again in 1912.

The lime requirements of the soil at different dates as indicated by the Veitch method were as follows:

| Lime requirements | of different | fertilizer plats in | -1904, 191 | 12, and 1914. |
|-------------------|--------------|---------------------|------------|---------------|
|-------------------|--------------|---------------------|------------|---------------|

| Kind of plat. | Calcium oxid required per acre of soil. | | |
|--|---|--|------------------------------|
| | 1904 | 1912 | 1914 |
| Unlimed ammonium sulphate plat Limed ammonium sulphate plat Unlimed sodium nitrate plat Limed sodium nitrate plat | $\begin{array}{c} Lbs. \\ 4,700 \\ 1,100 \\ 2,500 \\ 0 \end{array}$ | $Lbs. \\ 5,500 \\ 3,200 \\ 4,200 \\ 2,600$ | Lbs. 7,784 4,607 4,210 3,069 |

About 280 different kinds of plants have been grown upon the plats, classified as follows: Flowers (mostly perennials), 75; trees and small fruits, 25; grasses and clovers, 30; and miscellaneous crops, 150. The behavior of the different plants as regards the condition of the soil are presented in concise tabular form. It is shown that the behavior of the different plants toward liming is influenced to a marked extent by the residual effect of ammonium sulphate and sodium nitrate. The plants tested included those representing all grades, from such as are positively injured by an application of lime, even to a very acid soil, to such as are unable even to live on an acid soil and are greatly benefited by liming.

Prominent among the flowers which seemed to be quite tolerant of soil acidity were blue false indigo, marigold, tickseed, evergreen, Japanese bell flower, Nicotiana, scarlet sage, and catchfly. Of the trees tested Norway spruce, birch, and peach seemed to be particularly tolerant of soil acidity. Of the fruits the Blackcap raspberry was more productive on the unlimed than on the limed plats, whereas the opposite was true with the Cuthbert raspberry. The most pronounced case of injury from liming was represented by the cranberry.

Of the grasses redtop and Rhode Island bent grew well on the unlimed plats. The growth of the clovers varied with the source of nitrogen, some of them growing about equally well on the sodium nitrate plats whether lime was added or not. With the exception of cowpeas, lupines, serradella, and vetch the leguminous plants were, as a rule, however, benefited by lime. Japanese millet seemed to grow best on the most acid soil.

The conditions in these experiments were not such as to make it possible to compare the relative efficiency of ammonium sulphate and sodium nitrate as sources of nitrogen for the different crops since the reaction of the soil was not

optimum for the growth of the particular kind of plant under experiment. "To create such a condition there would usually be required the addition of a larger amount of lime in connection with sulphate of ammonia, because it is physiologically acid; and inasmuch as such larger amount has not thus far been applied in the present experiment, only those plants which prefer moderate soil acidity have usually grown better on the limed sulphate of ammonia plat than on the limed nitrate of soda plat, whereas the reverse is true of those plants which are sensitive to acidity. This indicates that in the present experiment the reaction of the soil may have had a more important influence on growth than the form of the nitrogen."

The use of lime on land, F. D. Gardner (Pennsylvania Sta. Bul. 131 (1914), pp. 171-204, figs. 3).—The wide distribution in Pennsylvania of acid soils, that is, soils on which clover fails, is pointed out, this condition being attributed to a deficiency of lime which may occur even in soils originally rich in lime. Reference is made to numerous tests which have shown that red clover fails when the lime requirement of the soil is 1.500 to 1.700 lbs. of burnt or caustic lime, equivalent to 2.700 to 3.000 lbs. of carbonate of lime or crushed limestone per acre to a depth of 7 in. On the other hand, red clover grows without serious check on a soil of which the lime requirement is only 500 to 1.000 lbs. per acre. In ordinary farm practice the acidity seldom becomes so marked as to affect noticeably the growth of cereals and grasses.

Pot experiments made by the station are cited to show that finely pulverized limestone is as prompt and effective in correcting soil acidity and promoting the growth of clover as equivalent amounts of caustic lime. The station field experiments extending over a long period of time showed a steady increase in the lime requirement and in the benefit from liming and that the lime requirement of soils is greatly increased by the continued use of ammonium sulphate. The field tests indicated no advantage in applying more than sufficient lime to neutralize the acids present in the soil and showed that large applications varying from 1,980 to 29,556 lbs, per acre were wasteful so far as the needs for five or six years are concerned. It was found that "the lime requirement indicated by the Veitch method falls about one-third short of the actual amount of lime advisable to apply under field conditions. This suggests that a third to a half more of lime should be applied in farm practice than is indicated by the Veitch method if the soil is to be neutral after one or two crops have been grown."

Fertilizer analyses, A. J. Patten, O. B. Winter, and O. F. Jensen (*Michigan Sta. Bul. 274 (1914*), pp. 3–28).—Analyses of 327 brands of fertilizers licensed for sale in Michigan in 1914 are reported, with a general discussion of the results of the inspection and the text of the state fertilizer law as amended in 1913.

The fertilizer inspection for 1914, B. E. Curry and T. O. Smith (New Hampshire Sta. Bul. 173 (1914), pp. 11).—Analyses of 184 brands of fertilizers offered for sale in New Hampshire during the year are reported. It is stated that these brands "almost without exception, have met their guaranty in every respect." Reference is made to a so-called mineral fertilizer, the approximate value of which, on the basis of analysis, was 60 cts. per ton, or one twenty-fifth of the price at which it sells wholesale.

Analyses and valuations of commercial fertilizers, fertilizer supplies, and home mixtures, C. S. Catheart et al. (New Jersey Stas. Bul. 272 (1914), pp. 43).—Analyses and valuations of 576 fertilizers and fertilizing materials, representing a portion of the brands of fertilizers collected and examined during the season of 1914, are reported and discussed.

AGRICULTURAL BOTANY.

Handbook of technique for teachers and students of natural science, B. Schmib (Handbuch der naturgeschichtlichen Technik. Leipsie: B. G. Tenbuer, 1914, pp. VIII+555, figs. 381).—This book, prepared by collaboration of the 15 authors named, is intended to bring together such information, directions, and suggestions as may prove helpful to instructors or students in any one of several branches of natural science. It is divided into sections partly corresponding to the usual divisions and the main requirements of such work in the field, laboratory, and museum, but partly grouping together features of more general application and common technique, as in photography.

The arrangement, preparation, care, and use of the laboratory, specimens, materials, and instruments, covering a wide range of studies, are treated in more or less detail. Lists are given of related scientific and pedagogic literature, and the work concludes with an index.

Culture media for use in the plate method of counting soil bacteria, II. J. Conn (New York State Sta. Tech. Bul. 38 (1914), pp. 34).—The author describes the use of two culture media, one of which is a soil-extract gelatin and the other an agar medium containing no organic matter except the agar, dextrose, and sodium asparaginate.

The soil-extract gelatin is recommended for use when the plate method is employed as a preliminary procedure in a qualitative study of soil bacteria. The chief advantage of the asparaginate agar is said to be that it contains no substance of indefinite composition except the agar itself. This, it is thought, would allow comparable results to be obtained by its use, even though the work was done in different laboratories by different individuals.

Four other media that have been recently discussed were compared with the media mentioned above, but for qualitative work they were all found to be inferior. For quantitative work they are said to be undesirable because they contain substances of indefinite composition.

The chemical dynamics of living protoplasm, W. J. V. OSTERHOUT (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 174).—The author claims it is possible, by means of electrical measurements, to follow reactions in living protoplasm without interference with the progress of the reaction or injury to the protoplasm. It is also considered possible to determine the order of the reaction and to ascertain whether the reaction is reversible. In many cases it appears that the reaction is reversible up to a certain point, but beyond this it is irreversible.

The mechanism of exchange between plants and external media, P. Mazé (Compt. Rend. Acad. Sci. [Paris], 159 (1914), No. 3. pp. 271–274).—Claiming to have shown previously (E. S. R., 31, p. 221) that the elaboration of a given weight of vegetable matter requires the use of a constant volume of nutritive solution of definite composition and concentration (this law dominating the whole economy of the plant and regulating exchanges with its external medium), also that roots excrete mineral and organic substances, this fact disagreeing with the hypothesis of a protoplasmic semipermeable membrane, the author gives tabulated results of a study on the rôle of osmosis in this connection as exemplified by maize growing in sun or shade and supplied with a nutritive medium including from 2 to 5 per cent of sugar.

The conclusion is drawn that the law of osmosis does not operate in any important degree to affect exchanges occurring between roots and nutritive solutions. The plant, it is held, constitutes a system permeable to water and to substances in solution or in colloidal suspension therein, but its per-

meability is essentially regulable not alone in the organs which are in relation with the external medium, but still more within the component tissues.

Evaporation and plant succession in southeastern Washington and adjacent Idaho, J. E. Weaver (Plant World, 17 (1914), No. 10, pp. 273-294, figs. 10).—A preliminary study, as detailed, of the differences of rates of evaporation in the various plant formations and associations in this region is considered to show that these differences are sufficient to be important factors in causing succession, at least through the earlier stages, where light values are usually high.

The effects of acid and alkaline solutions upon the water relation and the metabolism of plants, A. Dachnowski (Amer. Jour. Bot., 1 (1914), No. 8, pp. 412-439, figs. 4).—In extension of previous work (E. S. R., 31, p. 625), experiments are detailed as carried out to ascertain the possible importance of hydrolytic reactions in determining the amount of water absorbed and retained by plants during germination and growth, these experiments employing corn and bean seeds and tomato cuttings.

The results, which are given at length, are thought to justify the general conclusion that the variation in the water content of seeds can not be brought about solely through the concentration of acids and alkalis within the cells and tissues, and that the alterations here noted may be explainable on the hypothesis that hydrolytic changes are taking place whereby the water content in the seeds varies more and more as complete hydrolysis is approached. It is suggested that this work may aid in developing further the conception of antagonistic relations among salts.

 Λ bibliography is appended.

Root habits of desert plants and the reaction of roots to soil temperature, W. A. Cannon (Abs. in Science, n. ser., 41 (1915), No. 1048, pp. 173, 174).—According to the author there are three well-marked types of roots of desert perennials, those which never penetrate the ground deeply, those which penetrate the ground but have few or no roots near the surface, and those which are intermediate between these extreme forms. The relation of these different types of root systems to the temperature of the soils is discussed. It is thought that differences in temperature response, coupled with differences in soil temperature, are the definitive factors which bring about the characteristic distribution in the soil of the roots of the species studied.

Electrolytic determination of exosmosis from the roots of anesthetized plants, M. C. Merrill (Abs. in Science, n. ser., \$1 (1915), No. 1048. p. 176).— The author subjected growing plants of Pisum sativum to the influence of illuminating gas and ether vapor to determine their effect on exosmosis from the roots.

Where the roots were exposed directly to the anesthetics the resulting exosmosis was more rapid than where the roots were kept in water during the exposure. In the former case the root turgor decreased greatly, while in the latter case the tops were affected but the roots remained normal in appearance even though the exosmosis was abundant, thus indicating a disappearance of mineral nutrients from the tops. With older plants the increased conductivity was less than with younger plants, indicating a greater resistance to the anesthetics.

The germination of belladonna seed, A. F. Sievers (Amer. Jour. Pharm., 86 (1914), No. 11, pp. 483-505, figs. 10).—Detailing studies as carried out, the author states that freezing accelerates germination, that seed size shows no influence (but high specific gravity indicates high germinability), that color has no meaning in this connection, and that sulphuric acid treatment has no great

*

value as a means of increasing germinability. Scratching the seed coats with powdered glass or emery, while helpful, does not produce so good results as does treatment with hydrogen peroxid, which was of material benefit, the effect reaching the maximum at 60 per cent strength of the solution when applied to the seeds for not over 18 to 24 hours.

Pollen development in the grape with special reference to sterility, M. J. Dorsey (Minnesota Sta. But. 144 (1914), pp. 60, pls. 4).—A report is given of an investigation conducted to determine the cause of sterility in grapes and whether it can be controlled. As a basis of the investigation studies were made of the variety Brighton, which is said to be typical of a number of sterile or nearly sterile cultivated varieties of grapes. Comparisons are also made with the parent varieties from which Brighton was derived, as well as a number of other species and varieties.

The factors bearing upon the phenomenon of sterility were found capable of being divided into two classes, those inherent to the plant and those resulting from an unfavorable environment. In the grape the inherent cause of sterility was found to be due to the pollen rather than the pistil. Cytological studies of the pollen showed that sterile pollen in the grape results from degeneration processes in the generative nucleus or arrested development previous to mitosis in the microspore nucleus. Aborted pollen is found in varying quantities with both sterile and fertile pollen. It occurs in pure forms as well as in hybrids, but is usually more abundant in the latter. Since pollen is produced in abundance by the grape, aborted pollen is relatively unimportant from the standpoint of fertilization or the setting of fruit.

As a practical deduction from his investigations, the author states that as both fertile and sterile hybrids occur among the cultivated varieties of American grapes, hybridity is not necessarily a cause of sterility. It is evident that the cause of sterility in the grape is deep-seated and intimately connected with the functional activity of pollen, and can not be overcome by cultural conditions, but will have to be avoided by mixing varieties in the vineyard at planting time.

A bibliography is given.

Injury and abscission in Impatiens sultani, F. E. LLOYD (Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 6 (1913-14), pp. 72-79, figs. 11).—After noting contributions by others, the author gives results of his own studies with I. sultani.

Injury does not seem to cause abscission. The abscission layer lies just above the base of the internodes, but it is not strictly limited to any particular position, the point of its occurrence being determined physiologically. There is no special abscission tissue, the immediate cause of abscission being, it is claimed, the hydrolysis of the middle lamella, no disintegration of tissues occurring in any other sense. Increased turgor is claimed to play no part in this connection.

Some relations of plants to distilled water and certain dilute toxic solutions, M. C. Merrill. (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 176).—A determination was made of the interval during which pea seedlings could be left in redistilled water and in certain toxic solutions and then recover when later placed in a full nutrient solution. Horse beans (Vicia faba) were more marked than pea seedlings in their behavior toward the renewal of distilled water, those in which the distilled water was renewed showing more than double the growth. Bacterial and fungus action was found to be undoubtedly an important factor, and the evidence obtained indicates that there are several factors entering into the so-called harmful action of distilled water.

A study of vanadium and the action of vanadates in vegetables, E. C. RAMÍREZ (Datos Para et Estudio del Vanadio y Acción de Algunos Vanadatos en los Vegetales. Thesis, Univ. La Plata, 1914; abs. in An. Soc. Quím. Argentina, 2 (1914), No. 6, pp. 145, 146).—The author, after a general section on vanadium, a description of the principal vanadium bearing substances in Argentina, and a discussion of methods, gives an account of studies on vanadium as influencing vegetable growth, with the conclusion that this element may be absorbed and stored by plants, which may show anomalies of growth therefrom,

Arsenic and manganese in some vegetable products serving as animal food, F. Janin and A. Astave (Compt. Rend. Acad. Sci. [Paris], 159 (1914), No. 3, pp. 268-270).—In continuation of previous work (E. S. R., 29, p. 628), results are given in tabular form of analyses made of 12 plants (also of certain mixtures thereof) commonly fed to animals used for human food, indicating the percentages of arsenic and also those of manganese found in the fresh or the dry form of each.

On the correlation between somatic characters and fertility, J. A. Harris (Amer. Jour. Bot., 1 (1914), No. 8, pp. 398-411, figs. 4).—The author presents data hearing upon the relationship of somatic development (as measured by the fruits borne by the individual plant) to fruit fertility (as measured by the number of oyules forming and of seeds developing).

Data obtained and analyzed are considered to indicate that the correlation between number of pods per plant and number of ovules per pod is positive but low, and that the correlation between pods per plant and seeds per pod is for the most part positive and lower.

It is held that "there is some correlation between the number of pods per plant and the number of ovules which develop into seeds, which is in part at least independent of (although it may be inseparably bound up with) the morphogenetic factors which link together the magnitudes of the two characters," pods per plant and ovules per pod. This correlation is designated as more truly physiological than morphogenetic, although there is thought to be no very sharp line of demarcation between the physiological and morphogenetic in problems of the kind here considered.

Hybrids of Enothera biennis and E. franciscana in the first and second generations, B. M. Davis (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 177).— The author reports upon a study of 1.806 plants grown from reciprocal hybrids of the above species of Enothera. The second generation of this cross is said to present a wide range of forms, and among them were a number of plants with combinations of characters that appear to have fulfilled in essentials the requirements of synthetic E. lamarckiana-like hybrid.

Inventory of seeds and plants imported by the Office of Foreign Seed and Plant Introduction during the period from October 1 to December 31, 1912 (U. S. Dept. Agr., Bur. Plant Indus. Inventory No. 33 (1915), pp. 60, pls. 5).—This inventory gives a descriptive list of about 400 numbers of seeds and plants imported from various parts of the world for testing in the United States.

FIELD CROPS.

Grass pastures for irrigated lands, J. S. Welch (Idaho Sta. Bul. 80 (1914), pp. 15, figs. 3).—This bulletin describes methods of seeding, irrigating, and care of irrigated grass pastures in which Kentucky blue grass, smooth brome grass, orchard grass, timothy, meadow fescue, redtop, tall meadow out grass, English rye grass, Italian rye grass, Canada blue grass, white clover, alsike clover, and red clover were used singly and in mixtures. The value of these

grasses was measured by grazing tests with cows, sheep, and steers. Conclusions are given as follows:

Irrigated grass pastures produce returns that warrant their use even on comparatively high-priced land. Of all the grasses tested, Kentucky blue grass, smooth brome grass, orchard grass, timothy, and meadow fescue have proved the best.

"White, or alsike clover, is desirable in a very small proportion. More than three or four lbs, per acre may cause bloat. Mixtures give better results than any variety seeded alone. Different conditions require different mixtures. A total of about 28 lbs, of seed per acre is necessary.

"Seed should never be bought in mixtures. Thorough seed-bed preparation is absolutely essential. Grasses can be seeded any time from early spring to the middle of July. Fall seeding is not advisable. Broadcasting the different varieties separately is the most satisfactory method of seeding. The seed should be covered lightly with a spike-tooth harrow or good brush drag. Under average conditions a nurse crop should not be used.

"Irrigation water should be applied by the corrugation method during the first season; thereafter thooding between borders is recommended. The pasture should have frequent irrigation and during the entire season should receive a total of about 2.5 acre feet per acre. Early seeded pastures can be grazed lightly late in the first season. The pasture should be divided into at least two parts and should not be grazed too closely. Barnyard manner can be used on the pasture with good results. Some shade should be provided for the animals,

"Grazing tests at the station indicate that an acre of good mixed grass pasture will maintain two good dairy cows or three medium-sized beef steers during May, June, July, August, and part of September. The sheep grazing tests have not been very conclusive but indicate that an acre will maintain about 12 ewes and their lambs. The conclusions reached at the station are being substantiated by the experience of irrigation farmers in different parts of the State."

Soil fertility investigations, A. T. Wiancko (Indiana 8ta. Rpt. 1914, pp. 58-60).—Brief notes are given stating the successful use of soy beans and cowpeas in rotations to improve the soil fertility at the university farm and on the outlying fields of the State. As results of phosphate and manure treatments on the Scott County and Pike County fields it is noted that "the comparison of acid phosphate and raw rock phosphate used in conjunction with liberal liming has thus far shown that an application of 24 lbs. of phosphoric acid in acid phosphate once in three years is more profitable than a 2-ton application of raw rock phosphate put on at the rate of 1 ton per acre at the beginning of the experiment in 1906 and a second ton in 1911. The total value of the increase in eight corn crops and nine wheat crops, including straw and stover, and two clover hay crops which were removed from the land, has been \$87.41 for the acid phosphate and \$68.58 for the raw rock phosphate, yielding net profits of \$71.84 and \$54.58, respectively.

"Where ten tons per acre of manure were applied every three years on corn, the value of the increase was \$170.63 with a net profit of \$10.63 after allowing \$2 for each ton of manure used. Where two tons per acre of raw rock phosphate was added to the same manure treatment, the total value of the increase was only \$8.21 greater for the entire period and the net profit, after allowing \$2 per ton for the manure and \$7 per ton for the rock phosphate, was \$5.79 less than where manure alone was used. On the Pike County field, which was in a much better state of fertility to begin with, the addition of rock phosphate to the manure treatment showed only \$8.55 net returns for the

entire period, or approximately \$1 per acre per annum; the rock phosphate alone showed a loss of \$3.57, while the acid phosphate alone showed a gain of \$2.41 during the same period.

"These experiments, therefore, indicate that under the conditions prevailing on these two fields acid phosphate is more profitable as a source of phosphorus than is raw rock phosphate."

Report of the division of farm crops, V. M. Shoesmith (*Michigan Sta. Rpt. 1914, pp. 235–239*).—In this report F. A. Sprogg notes that two strains of winter barley have been developed to withstand Michigan winters satisfactorily. The improvements of wheat, oats, corn, and alfalfa as results of breeding and selection work are also briefly noted.

Data are given showing results in fertilizer experiments with wheat and corn, and in rotation experiments. It is stated, however, that these experiments have not been carried on long enough to justify conclusions.

[Experiments with field crops], P. VAN HOEK (Verstay, en Meded, Dir. Landb, Dept. Landb, Nijr, en Handel, No. 3 (1914), pp. 47-154).—Results of a variety test of potatoes for starch manufacture and of table potatoes are given, the latter being grown on both clay and sandy soils. The starch content of the former kinds ranged from 15.7 to 16.15 per cent.

The data show a considerable increase in yield, especially of marketable size tubers, as a result of seed selections. Results of spraying with Bordeaux mixture showed large increases, especially in the marketable sizes of the sprayed crops. In tests of the use of from 400 to 900 kg, per hectare (356 to 801 lbs. per acre) of nitrate of soda, covering the years 1908–1912, it was found that about 600 kg, gave the most profitable results.

Variety tests of sugar beets covering the years 1907-1911 are reported.

Studies of the influence of the application of from 200 to 600 kg, per hectare of nitrate of soda on the sugar content of beets for the years 1910–1912 showed a lack of uniformity.

The results of variety and manurial tests with mangels and turnips, cereals, beans, peas, flax, and of a test of inoculation of legumes and spraying for weed destruction are given.

In several years' experiments with grass lands a top-dressing of kainit and slag meal gave no results the first year. Kainit alone nearly doubled the yield, slag meal alone gave no increase, while 2 parts (1.000 kg. per hectare) kainit and 1 part of slag meal proved better than 1 part kainit and 2 parts of slag meal.

An application of sand to grass plats in the dry year 1911 caused an increase in yield in general on various fertilizer plats and improved the quality of the growth. In manurial tests complete commercial fertilizer on grass lands during 1899–1912 gave better results than barnyard manure or loam dressing.

Varietal tests 1914—ground nuts, maize, and rice, F. A. STOCKDALE (Dept. Agr. Mauritius, Gen. Ser., Bul. 3 (1914) [English Ed.], pp. 10).—This bulletin reports yields and analyses of several varieties of peanuts and maize and yields of several varieties of rice.

On the plant food absorption and growth of Agropyrum repens, H. Burmester (Fühling's Landw. Ztg., 63 (1914). No. 16, pp. 547-556, fig. 1).— This article describes pot experiments designed to determine to what extent A. repens suffers by deep covering of the rhizomes, to what extent it withdraws plant food from soils of varying fertility, and to what extent a crop suffers in its presence on soils of varying fertility. The following results are given:

When the rhizomes of A. repens are covered to a depth of about 12 in. they die. Repeated removals of the leaves of the plant above ground so weakens it

that it will soon die: A. repens withdraws abundantly available plant food in proportion to the fertility of the soil, but without appreciable increase in growth of its top. A crop of good stand (oats) prevented A. repens from withdrawing appreciable large quantities of plant food from a fertile soil and was little injured by its presence, and scarcely any more plant food was removed from the soil by the association than by oats alone.

Cultivation and composition of comfrey (Symphytum asperrimum) (Cultura, 26 (1914), No. 315, pp. 362-366).—This article briefly discusses the cultivation of this crop, and gives analyses and yields of a Caucasian variety, harvested at different dates throughout the season. The results of this work, performed at the seed-control station at Wageningen, are given in tabular form.

Corn judging, R. A. Moore (Wisconsin 8ta, Circ. 8 (1913), 2, rev. ed., pp. 23, figs. 11).—A revised and enlarged edition (E. S. R., 22, p. 233).

Variety work with corn and cotton, C. K. McClelland (Georgia Sta. Bul. 113 (1915), pp. 249-256, figs. 2).—Data showing the number of 2-eared stalks, number of barren stalks, and the yield and percentage of corn to ear from 14 varieties of corn for 1914 are given and briefly discussed. The yields ranged from 16.1 to 23.9 bu, per acre, and the percentage of corn to ear from 80.5 to 90.9. The highest yielding variety, Velvet Cob, produced ears averaging 88.5 per cent corn.

The results of testing 32 varieties show yields of seed cotton per acre ranging from 842 lbs. to 1,295 lbs. and the percentage at first picking from 33 to 77. The variety Sawyer Improved, producing the highest yield of lint, 442 lbs. per acre, showed 37 per cent lint and 56 per cent at first picking. The variety Perry Improved, showing the highest percentage at the first picking, gave a yield of only 278 lbs. of lint per acre.

Cowpeas in the cotton belt, W. J. Morse (U. S. Dept. Agr., Off. Sec. Spec. [Circ.], 1915, Feb. 13, pp. 5).—This gives cultural methods and uses.

The dasheen, a root crop for the South, R. A. Young (U. S. Dept. Agr., Bur. Plant Indus. Doc. 1110 (1914), pp. 11, pls. 4).—A revision and extension of a paper previously noted (E. S. R., 29, p. 336).

Report of experiments with oat varieties at the Stockholm experiment fields for the period 1908–1912, S. Rhodin (Meddel, Centralanst, Försöksv, Jordbruksområdet, No. 100 (1914), pp. 16; K. Landtbr, Akad, Handl, och Tidskr., 53 (1914), No. 6, pp. 435–448).—This article gives results obtained with 15 varieties of early, medium, and late maturing oats. Tabulated data include the yield of grain and straw, days to maturity, dry weight, green weight, weight per hectoliter, and percentage of hull.

The average yields of grain for the different varieties for the period ranged from 2,835 kg. (2,523 lbs. per acre) to 3.779 kg. per hectare, while the percentage of hull varied from 25 to 31.6 per cent. The percentage of hull showed no correlation with the grain yield. The best yielding variety showed the highest percentage of hull, thus making it in actual value the most inferior of all the varieties tested.

Home-mulched vs. northern seed potatoes for eastern Nebraska, R. A. EMERSON (Nebraska Sta. Bul. 146 (1914), pp. 5-36, fig. 1).—" Experiments carried on at this station show clearly that it is possible to increase the productiveness of potatoes by proper methods of breeding. But potato breeding can not be carried on successfully unless the same stock of potatoes can be kept indefinitely. This can not be done in southern and eastern Nebraska with ordinary methods of culture. The importance of producing improved strains of potatoes for this region makes it desirable to devise a method of producing strong seed tubers at home.

"Since rather low and fairly uniform soil temperatures seem to be essential to the production of high-class seed tubers, the use of a mulch of straw or other coarse material about the plant suggested itself. This method has been under test at the station for eight years, and during that time 22 separate tests have been conducted, all with the Early Ohio variety. In every test a uniform stock of tubers was divided into two lots, one grown by ordinary cultivation and the other one mulched. The seed tubers produced on the two plats were kept under identical conditions over winter. The next spring both were planted in the same way on adjoining plats of as uniform soil as could be had, and both were given the same cultivation throughout the summer. Differences in yield the second year of the test are, therefore, attributable to the different methods of culture by which the seed tubers were produced in the tirst year of the test. Tests were also made of the effect of different numbers of years of mulching and cultivation.

"In ten comparisons of seed tubers grown one year under a mulch with seed tubers of the same stock grown one year by ordinary cultivation, for each 100 lbs, of tubers produced from mulched seed the cultivated seed produced 62, 68, 70, 70, 76, 80, 82, 83, 88, and 93 lbs., respectively, or an average of 77 lbs. The other 12 tests compared from two to eight years of mulching with the same number of years of cultivation. The results from all the 22 tests are that for each 100 lbs, of marketable tubers grown from mulched seed the average yields of marketable tubers from cultivated seeds were: Cultivated 1 year (10 tests), 77 lbs.; 2 years (4 tests), 68 lbs.; 3 years (1 test), 74 lbs.; 4 years (1 test), 68 lbs.; 5 years (1 test), 54 lbs.; 6 years (2 tests), 49 lbs.; 8 years (1 test), 54 lbs.

"Continued cultivation in sontheastern Nebraska results, then, in a pronounced though somewhat gradual deterioration of potato stocks. One year of mulching, however, restores the normal vigor of the stock, as is indicated by two tests as follows: Mulched 6 and 7 years, 100 lbs.; mulched 5 and 6 years and cultivated 1 year, 82 lbs.; cultivated 6 and 7 years, 67 lbs.; cultivated 5 and 6 years and mulched 1 year, 100 lbs.

"Comparisons of home-grown mulched stocks of Early Ohio potatoes with northern-grown stocks of the same variety have been made in five of the eight years. For each 100 lbs. produced on the average by mulched seed tubers, the northern-grown seed tubers yielded an average of 98 lbs.

"Northern-grown seed tubers ordinarily retail for about 25 per cent more than home-grown tubers. The estimated cost of producing seed tubers by mulching is \$10 to \$12 an acre more than the cost of producing them by cultivation, but a mulched seed plat will ordinarily yield about 25 per cent more seed tubers an acre than will a cultivated seed plat. The cost per bushel is, therefore, not greatly different for the two methods. The grower can produce high-class seed tubers at home by mulching at a cost somewhat less than he can buy northern-grown seed of equal quality.

"It is recommended to mulch a few rows of potatoes along one side of the field to furnish seed for the next year's crop. The mulch should be about 4 in, deep after settling and may consist of hay, straw, stable litter, or other coarse material free from grain and noxious weed seeds. It is best applied before the plants come up and must be spread by the time the new tubers begin to develop. To insure that the plants are strong enough to push up through the mulch and to produce as large a yield as possible for a given amount of mulching, large seed pieces from 4 to 6 oz. should be planted. The depth of planting should be the same as in the rest of the field, about 4 in."

The use of Paris green and Bordeaux on the farm, J. W. INCE (North Dakota Sta. Spec. Bul., 3 (1915), No. 14, pp. 239, 240).—This article briefly de-

scribes these and other spray mixtures, the methods of application, and the effect on the potato crop.

The fractional liquefaction of rice starch, F. J. WARTH and D. B. DARABSETT (Mem. Dept. Agr. India, Chem. Ser., 3 (1914), No. 5, pp. 135-146, pl. 1, fig. 1).— This paper describes a method of fractional liquefaction of rice starch and its application in differentiating seven varieties of rice. The method involves a wet grinding of the grain and fractional liquefaction of the starch in water at different temperatures for definite periods of time and a conversion secured with malt extract. The samples showed decided degrees of liquefactions at the various periods and uniformity for the same variety.

Field tests of soy beans, 1914 (Connecticut State Sta. Bul. 185 (1915), pp. 3-17).—This bulletin briefly discusses the uses of the soy bean as a catch crop, green manure crop, seed crop, silage crop, and for hay for Connecticut farmers, and gives results of tests of 1914 that were planned and carried out by H. K. Hayes and C. D. Hubbell, showing analytical data and composition in comparison with corn and alfalfa.

Data of 19 varieties grown as forage show the total yields to range from 5,389 lbs. to 21,240 lbs., averaging 16,949 lbs. per acre, and the dry matter to range from 1,247 lbs. to 6,287 lbs.

The protein ranged from 2.7 to 7.1 per cent with an average of 4.8, fat from 0.7 to 2.6 with an average of 1.6, nitrogen-free extract from 8.8 to 15.5 with an average of 11.7, and fiber from 4.9 to 12.3 with an average of 8.6.

The highest yielding variety in grain produced 32.5 bu, per acre. Analyses of the grains show the protein to range from 36.8 to 45.5 per cent, fat from 14.1 to 19 per cent, ash from 5.2 to 8.6 per cent, nitrogen-free extract from 26.2 to 32.9 per cent, and fiber from 4 to 6.5 per cent.

The composition and digestible nutrients of soy beans, cotton-seed meal, and linseed meal are compared. Methods of planting soy beans are discussed briefly. The Hollybrook variety is recommended for Connecticut conditions as a crop for soiling, hay, or green manure.

Physiological changes in sweet potatoes during storage, H. HASSELBRING and L. A. HAWKINS (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 4, pp. 331-342).—The results of the investigations conducted at Washington, D. C., with Jersey Big Stem and Southern Queen sweet potatoes are summarized as follows:

"During its growth the sweet potato root is characterized by a very low sugar content. The reserve materials from the vines are almost wholly deposited as starch.

"Immediately after the roots are harvested there occurs a rapid transformation of starch into cane sugar and reducing sugars. This initial transformation seems to be due to internal causes and is largely independent of external conditions. Even at a temperature of 30° C. (86° F.) both cane sugar and reducing sugars accumulate during this initial period in excess of the quantity used in respiration, while during subsequent periods the quantity of reducing sugar diminishes at that temperature as a result of respiration. These initial changes seem to be associated with the cessation of the flow of materials from the vines.

"In sweet potatoes stored at a temperature of 11.7 to 16.7° the moisture content remains fairly constant. There is a gradual disappearance of starch during the first of the season (October to March) and probably a re-formation of starch accompanied by a disappearance of cane sugar during the latter part of the season (March to June). The changes in reducing sugar are less marked than those in cane sugar. The changes in starch and cane sugar appear in a general way to be correlated with the seasonal changes in the temperature.

"In sweet potatoes kept in cold storage (4° C.) there is a rapid disappearance of the starch and an accompanying increase in cane sugar. These changes do not attain a state of equilibrium at that temperature, as the sweet potatoes invariably rot by the action of fungi before the changes have reached their maximum. At both high and low temperatures cane sugar is the chief product formed by the conversion of starch in the sweet potato. The quantity of invert sugar in the root at any time is comparatively small."

A bibliography of cited literature is appended.

On the spike form of wheat, L. Detzel (Fühling's Landur, Zty., 63 (1914), No. 17, pp. 561–572).—This article discusses the different forms of spikes of wheats, the arrangements of the spikelets, and the factors which cause the different forms. Statistical data of different type forms are given and the application of the formula $D=\frac{x.100}{y}+1$ in which D represents the thickness, x the number of spaces between the spikelets on one side of the spike, and y the length of the spike axis is explained.

Is the present system of grading wheat equitable? E. F. Ladd (North Dakota Sta, Spec, But., 3 (1915), No. 14, pp. 233-239).—This article criticizes the present market grades of wheat and presents data, compiled as joint cooperative work of the station and this Department, to show that millers, on the basis of their net returns for thour and by-products, could pay more for the lower grades and thus return a large sum to the growers.

Root atlas, B. Schulze (Wurzelatlas, Berlin: Paul Parey, 1911, vol. 1, pp. 36, pls. 36; 1914, vol. 2, pp. 42, pls. 29).—Volume 1 contains 36 plates from photographs, showing the root systems at different stages of growth of winter and spring rye, winter and spring wheat, oats, and barley, and volume 2 contains 29 corresponding plates for peas, horse beans, white lupine, red clover, and winter rape. Each volume also contains statistics showing the length and weights of roots, length and weights of tops, and ratios between roots and tops for the individual plants, and a text discussing the work. See also a previous note (E. S. R., 31, p. 733).

The longevity of some common seeds, A. Eastham (Agr. Gaz. Canada, 1 (1914), No. 7, pp. 544-546).—This paper gives results of germination tests of seeds of timothy, red clover, and alsike clover, that had been stored 10 years, and of oats that had been stored 13 years.

For timothy it is noted that "the average germination of the 25 samples 1 year after harvest was 95 per cent; 5 years after, the average was 90 per cent; after that, however, a steady loss of vitality was shown, although at the end of 10 years an average germination of 54 per cent was still shown. It is interesting to note that, contrary to general opinion, the timothy seed retained its vitality somewhat better than either red clover or alsike."

For red clover "the average germination of 24 samples 1 year after harvest was 97 per cent, while 10 years after, only 44 per cent was capable of germination."

For alsike clover "the average germination of 24 samples 1 year after harvest was 93 per cent, and 10 years after, 45 per cent, or a loss of 48 per cent during that period."

For oats "the average of the 180 samples when first tested in 1903 was 95 per cent, while the average of 156 samples (the supply of seed in 24 samples having become exhausted) when 10 years old was still 95 per cent. Furthermore, the average germination of 53 samples 13 years old was 91 per cent, an average loss of only 4 per cent during that period, a very slight loss when we remember that in ordinary germination work a variation of 5 per cent is allowable between tests on identical lots of seed."

Report of seed analysis, Bertha A. Hollister (Ann. Rpt. Sec. Bd. Agr. Mich. 53 (1914), pp. 168-182, figs. 6).—This gives the results of the purity analyses of agricultural seeds under a new law, and the text of the regulation for seed testing.

First annual seed laboratory report, 1913–14, W. L. Oswald (Minnesota Sta. Bul. 147 (1915), pp. 5–20, figs. 6).—This bulletin discusses the Minnesota seed law and its effect upon the seed industry of the State, points out the functions of the educational, experimental, seed testing, and seed inspection divisions of the seed laboratory, and gives results of seed testing for germination and purity for 1913–14.

Results of seed tests for 1914, F. W. Taylor (New Hampshire Sta. Bul. 174 (1914), pp. 20, fig. 1).—This gives results of purity and germination tests of 126 samples of seeds examined from September 1, 1913, to September 1, 1914, with brief notes.

Wisconsin seed inspection law, A. L. Stone (Wisconsin Sta. Circ. Inform. 4 (1911), 2. ed., pp. 10, fig. 1).—A slightly revised edition (E. S. R., 22, p. 236).

The new seed inspection law, A. L. Stone (Wisconsin Sta. Circ. Inform. 4 (1913), Sup., pp. 3).—A brief discussion of the changes made in 1913 in the above law.

HORTICULTURE.

[Report of horticultural investigations], F. Garcia (New Mexico 8ta, Rpt. 1914, pp. 58-67, 72-74, figs. 3).—This comprises brief statements of the progress made with the various horticultural projects in 1913, and in part noted in a previous bulletin (E. S. R., 30, p. 839).

Experiments with Vinifera grapes have shown plainly the benefit derived from covering the vines during the winter. Uncovered vines in both irrigated and nonirrigated plats were badly winter injured, the canes being killed back to the ground. Data are given for 1913 showing the yields on the various grape plats. A table is also given showing the comparative growth made during the season of 1- and 2-year-old apple grafts planted in 1912. The fertilizer experiments with peach trees were continued, and the results as measured by tree growth during 1912 and 1913 are briefly recorded. In the orchard cover crop experiment plantings of various crops were made on October 15 and December 1, 1913, and on January, February, and March 1, 1914. A diagram is given showing the height of these various plantings when plowed under on May 11. Of the various peas planted on October 15, sweet peas alone passed through the winter uninjured and the amount of vine growth in May was equal to that of the various pea plantings made on December 1. Some data are given on cultural and variety tests of spinach and cauliflower.

Breeding experiments with the Mexican chili were continued. A number of promising strains were secured and are here illustrated. Data are given showing the yields of fresh, red, and green chilies, together with the estimated yield per acre of good dried red chilies secured from the various strains in 1913.

Fertilizer tests on onion lands, A. G. B. Bouquet (*Oregon Sta. Bicn. Crop Pest and Hort. Rpt. 1913–14, pp. 7–24, figs. 4*).—The results are given of cooperative fertilizer experiments with onions conducted on a number of farms in the upper Willamette Valley during the seasons 1913 and 1914. The results thus far show in general that expenditures for medium heavy to heavy applications of fertilizer are not always accompanied by resulting crop increase. Each farm is an individual problem and in few cases can a definite rule of fertilization be economically applied to all. The experiments are being continued.

Tomatoes, H. P. STUCKEY (Georgia Sta, Bul. 112 (1915), pp. 209-248, figs. 14).—A revision of Bulletin 96 of the station (E. S. R., 26, pp. 640, 648). Historical references and variety tables are either condensed or omitted in the present bulletin and the descriptions of varieties are omitted entirely. Some additional data on tests of early varieties, noted in Bulletin 106 of the station (E. S. R., 31, p. 438), together with directions for the control of insect pests and fungus diseases, have been added to bring the subject matter up to date.

Tomato growing in the South, H. C. Thomrson (U. 8, Dept. Agr., Farmers' Bul. 642 (1915), pp. 13, figs. 9).—A popular treatise on tomato culture prepared with special reference to the needs of canning clubs and those who grow tomatoes for home use. It discusses the starting of tomatoes in hotbeds and cold frames, soils and their preparation, manures and fertilizers, planting, cultivation, pruning and staking, rotation, diseases and their control, varieties, cost of growing, yields, and returns,

Greenhouse tomato investigations, A. G. B. Bouquer (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 25-34, figs. 3).—A progress report on the station's investigations with tomatoes (E. S. R., 29, p. 145) in which the results obtained from crops produced during the years 1912-1911, inclusive, are discussed.

The results in general show that tomato varieties differ quite largely in the amount of fruit produced during various stages of the bearing season. In the three years of test Bonny Best, Jewel, Earliana, and Sutton $\Delta 1$ in the order named have been the most desirable varieties from the standpoint of early and prolific production.

Early yields of tomatoes are greatly influenced by pollination. Both hand pollination and shaking the vines resulted in profitable net increases over plants that were left untouched. The total amount of tomatoes for the season is largely decreased where no assistance is given in pollinating the vines.

Actual counts were taken of a large number of flower clusters of various varieties, and it was found that nearly 50 per cent of the blossoms remained unfertilized. The profitic bearing habits of varieties appear to be affected by the number of blossoms ordinarily produced on clusters. Data are given showing the variations in this respect of the varieties tested, together with a general summary of variety characteristics.

Ringing fruit trees, G. H. Howe (New York State Sta. Bul. 391 (1914), pp. 575-584, pl. 1).—In some previous investigations conducted at the station (E. S. R., 19, p. 37) it was found that ringing herbaceous plants was so deleterious to their growth that it could not be advocated for general practice. The object of the experiments here reported was to determine the extent to which fruit trees can be ringed without permanent injury and to what degree the operation induces and stimulates fruitfulness. Apples, pears, plums, and cherries were used in the work which was started in 1910 and carried on during the three succeeding years.

The results as a whole indicate that under certain conditions ringing may induce and possibly increase fruitfulness of apples but it rarely has these favorable effects on other fruits. The practice of ringing stone fruits should never be followed, the experiments indicating almost 100 per cent loss in the life of the trees. Only young and very vigorous apple trees and possibly now and then pear and cherry trees can survive ringing. There are no regular and successive increases in productiveness and ringing had no apparent influence upon the size, color, or maturity of apples. The general effect of ringing on the roots of trees was to increase their size, and number and to lessen their vigor. The results obtained are not favorable to ringing fruit trees as a general practice.

Ringing an unsafe stimulus to fruit bearing, F. H. Hall (New York State Sta. Bul. 391, popular ed. (1914), pp. 4).—A popular edition of the above.

Spraying farm orchards by the club plan, R. D. Jay and W. M. Cook (Ohio Sta. Circ. 148 (1914), pp. 45-52).—This circular describes a cost accounting experiment conducted by the station in cooperation with the Greene County Improvement Association in order to secure data relative to the community spraying of orchards by one man. An itemized account is given of the overhead charges connected with the work, together with an itemized statement of the expense incurred in spraying one orchard and summarized statements of the cost in the seven other orchards.

The total cost per tree for three sprays was 44.3 ets, and the total amount of spray material required per tree for three sprays was 0.7 gal. lime-sulphur and 0.2 lb. lead arsenale. The average number of trees sprayed per hour was 18, including the time spent in mixing the material and filling the tank. Under favorable conditions it was found possible to spray 300 trees in a day. The total rental charges for the spray outfit amounted to \$58.86, which allows 6 per cent on an investment of \$150, as well as 20 per cent depreciation, and leaves about \$18 a year for repairs, insurance, and storage charges.

Some suggestions based on the present work are given with a view to assisting those organizing orchard spraying clubs.

Spraying program for orchards with combinations recommended, W. J. Green, A. D. Selby, and H. A. Gossard (Ohio Sta. Circ. 149 (1915), pp. 53-60).—This circular contains schedules for spraying orchards of apple, pear, plum, and peach, the directions being based upon many years of observations and experimental testing.

Spray treatment, etc., for orchards, W. E. Britton and G. P. Clinton (Connecticut State Sta. But. 184 (1914), pp. 3-12).—This bulletin describes the general spraying practice for the treatment of the apple, pear, peach, plum, cherry, and quince, and gives directions for making spray mixtures.

Spray calendar, W. E. Britton and G. P. Clinton (Connecticut State Sta. Bul. 183 (1915), pp. 32, figs. 63).—This calendar contains directions for the control of the more important insect pests and diseases of orchard and small fruits, vegetables, and other plants, including also formulas for the preparation of spray mixtures.

Tree fillings and wound dressings for orchard and shade trees, A. D. Selby (Ohio Sta. Circ. 150 (1915), pp. 61-63).—This circular describes the process of filling cavities in branches and trunks with a composition of asphaltum and sawdust, a method originated by J. Boddy. Instructions are also given for dressing wounds with gas tar and liquid asphaltum.

Thinning apples, H. J. Eustace (Michigan Sta. Circ. 24 (1914), pp. 158-160, flgs. 2).—This circular contains practical suggestions relative to thinning apples. Some data are given showing the time required to thin fruits of four Wealthy apple trees. On one tree 2.980 fruits were removed in two hours time. This tree yielded 19 bu. of marketable fruit and 2.5 bu. of culls at harvest time.

An inquiry into the nature of a somatic segregation of characters in the LeConte pear, W. P. Tufts (Oregon Sta. Bul. 123 (1914), pp. 4–16, figs. 6).— The author cites several recorded instances of variation of characters in somatic tissue, and gives the results of a study conducted with the LeConte pear with the view of throwing some light on the general laws underlying somatic variations. The somatic segregation here considered has to do with the relative deciduousness or persistence of calyx lobes in the LeConte pear. Observations were made throughout the fruiting season on the crop of one tree, amounting to 5,396 fruits, each of which was considered as 5 fruits when

determining the deciduous or persistent nature of the calyx lobe. A similar study with 56 fruits of the Transcendent crab apple was also made.

An examination of the data secured with both fruits showed a striking similarity in the segregation of the decidnous and persistent factors to that secured in an F₂ Mendelian hybrid. The decidnous factor dominated in the pear at the ratio of 1:3.7 and in the crab apple at the ratio of 1:2.8. Partial evidence is presented to show that the failure of the segregation in the LeConte pear to assume that of a characteristic F₁ Mendelian hybrid, i. e., the complete dominance of the decidnous factor, may be due to the possibility of either one or both of the supposed parents. Pyrus sincusis and P. communis, carrying both a factor for decidnousness and a factor for persistence. Out of 250 varieties of supposedly pure P. communis studied, 31 per cent sometimes shows a tendency toward decidnous calyx lobes. The author concludes in brief that since the Mendelian ratio is so closely approximated, it is reasonable to consider the LeConte a true hybrid between the species P. communis and P. sinensis.

Assuming, however, that the LeConte is a mere mutation of *P. sinensis*, "the data show that there is apparently a mechanism possessed by the somatic cell capable of affording practically the same results and with the same degree of regularity as those afforded by the reduction and fertilization processes incident to bisexual reproduction." It is suggested that this hypothesis may explain the immediate causes of at least some bud variations, and the inquiry as a whole is offered as a contribution to our present limited data on bud variation.

A bibliography of the cited literature is given.

The pear as affected by moisture supply, A. F. Barss (Oregon Sta. Bien. Crop Pest and Hort, Rpt, 1913-14, pp. 38-49, figs. 4).—The results for the first two seasons are given of experiments conducted to determine the effect of varying amounts of water upon the growth and fruiting habit of pear trees.

A test was conducted with 48 uniform dwarf Bartlett pear trees growing in pots under controlled conditions. One lot of pots was kept standing in water in order to insure a continuous supply. Another lot of trees received just as much water as was needed to keep up the supply for the first lot, but the water was applied in twice as frequent applications of one-half the quantity each time. The trees in the third lot received half as much water as for the first two lots. The trees of the fourth lot received just enough water to keep them alive.

The results for the first year showed no perceptible difference between the different lots of trees in the time required for the trees to leaf out fully. Trees receiving the maximum amount of water developed larger and more brightly colored leaves than the trees receiving half the amount. Trees given the minimum amount of water developed small, dull, grayish-green leaves. All of the trees started to form terminal buds at the same time, but these buds grew out again on some of the fully watered trees, thus indicating that large increases in the amount of water above the minimum required by the trees lengthen the Generally speaking, the amount of wood growth increased growing season. with the amount of water supplied, although the difference was not great in the two lots receiving the least amount of water. The lenticels of trees receiving the greatest amount of water were larger and more conspicuous and the growing wood showed more green than on the trees receiving half the amount. When matured and dormant, the wood on the trees receiving the full amount of water was darker and showed less green than the wood on the trees receiving half the amount of water. Late growths put out by the trees receiving the continuous supply of water remained green through the winter.

During the second season measurements and observations were made at frequent intervals to determine any existing differences in condition of trees, in

blooming, fruit development, new branch growth, foliage, etc. The differences observed are here presented and discussed. As summarized they show that thus far for the two years of experiment the water supply did not influence the time of starting of buds. The trees which received an excess of water showed the greatest number of blossom clusters; greatest average size, greatest average weight, and highest quality of fruit; greatest total amount of wood growth; greatest number of branches; greatest average linear growth to the branch; greatest average diameter of wood growth; longest internodal spaces; greatest number of cases of multiple growths from single buds; largest, most conspicuous, and greatest number of lenticels; greatest size, weight, and vigor of leaves; greatest number of leaves affected with the apparent "sunburn"; longest growing season; largest, healthiest, and most vigorous buds; and readiest formation of callus tissue. The moderately watered trees had the largest total number of blossoms and greatest number of fruits. The scantily watered trees led the others only in having the largest average number of flowers to the cluster. "Of the lots which received the excess of water, the one which received water less frequently showed a superiority only in that it had the greater number of fruits, greater average weight to the leaf, and greater average diameter of new growth. On the other hand, the lot watered more frequently slightly exceeded the other in all other respects."

Blackberry culture, G. M. Darrow (U. S. Dept. Agr., Farmers' Bul. 643 (1915), pp. 13, figs. 8).—A practical treatise on blackberry culture, discussing the location of the plantation, soils and their preparation, propagation, pollination, planting, intercrops, cultivation, fertilizers, systems of training, mulching, harvesting, yields, winter protection, duration of plantation, insects and diseases, regional adaptability of varieties, hybrids and novelties, and blackberry by-products. In the introduction statistics are given showing the acreage devoted to the cultivation of blackberries and dewberries in the United States in 1909.

Strawberry varieties in Oregon, V. R. Gardner (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 50-94, fig. 1).—This comprises descriptive notes on varieties of strawberries which have been tested at the station during the period 1908 to 1913, inclusive. The characters described are such as have to do with the horticultural value of both plant and fruit. Reference is made to the history of each variety as far as known. A bibliography of cited references is appended.

FORESTRY.

The temperature of leaves of Pinus in winter, J. H. EHLERS (Amer. Jour. Bot., 2 (1915), No. 1, pp. 32-70, figs. 4).—Results are given of an investigation conducted in the arboretum of the University of Michigan with the view of determining the internal temperature of pine leaves in winter under as nearly natural conditions as possible. The species Pinus laricio austriaca was selected for the purpose, the leaves of this species being the largest in cross section of the conifer leaves available in the locality. An attempt was also made to obtain direct evidence of photosynthesis under winter conditions by examining for starch content the leaves of the various conifers growing in the university arboretum.

The data here presented show that evergreen conifer leaves even under winter conditions maintain through the absorption of radiant energy temperatures from 2 to 10° C. higher than the surrounding air. The maximum obtained under brilliant illumination and with a light breeze blowing was 8.83°. Where the leaf

was partially protected against air currents a differential temperature of 10.31° was obtained. Even diffuse light according to its brightness will increase the leaf temperature from 0.5 to 2°. The average differential temperature for February, the coldest month of the year, based on some 650 readings taken between the hours of 8 a. m. and 3 p. m. was 3.06°.

Although these differential temperatures are considerably less than those obtained by previous investigators for broad leaves under summer and tropical insolation the differences are believed to be of sufficient magnitude to become an important factor in photosynthesis. More or less starch was found in various conifers examined during the winter although no conclusive evidence of starch formation was observed after December 13. This result, it is suggested, merely indicates that photosynthesis was not sufficiently active under the conditions that obtained during January and February to result in the production of starch in the leaf. Carbohydrates may have been formed and used or translocated as fast as formed.

The literature of the subject is reviewed under the general headings of the internal temperature of foliage leaves, photosynthesis and low temperatures, and accumulation of reserve food material by evergreen trees in winter.

A bibliography of consulted literature is appended.

Report on forest administration in Burma for the year 1912–13, C. G. Rogers (Rpt. Forest Admin. Burma, 1912–13, pp. 111+4+149).—A progress report on the administration of the state forests in Burma, including a financial statement for the year 1912–13. The important data relative to alterations in forest areas, forest surveys, working plans, forest protection, silvicultural operations, miscellaneous work, yields in major and minor forest products, revenues, expenditures, etc., are appended in tabular form.

Annual progress report on forest administration in the Presidency of Bengal for the year 1912–13, C. E. Muriel (Ann. Rpt. Forest Admin. Bengal, 1912–13, pp. 11+45+4. pl. 1).—A report similar to the above relative to the administration of the state forests of Bengal for the year 1912–13.

Progress report on forest administration in the Northwest Frontier Province for 1913–14, W. Mayes (Rpt. Forest Admin. Northwest Frontier Prov., 1913–14, pp. 2+II+16+XXVI).—A report similar to the above relative to the administration of the state forests of the Northwest Frontier Province for the year 1913–14.

DISEASES OF PLANTS.

How saprophytic fungi may become parasites, G. Massee (Roy. Bot. Gard. Kew, Bul. Misc. Inform. No. 5 (1914), pp. 190, 191).—A case is described in which Clerodendron fallax at Kew had been attacked by Cladosporium epiphyllum under conditions favorable thereto. This had apparently started as a saprophyte on the stalked peltate leaf glands excreting a nutritive liquid, and appeared to have developed the parasitic habit within three weeks. It is thought that opportunities for habitually saprophytic but potentially parasitic fungi to change their habit are numerous in nature, very slight changes of conditions being sufficient to initiate the parasitic activity.

Parasitism in Hymenochæte agglutinans, A. H. Graves (Myeologia, 6 (1914), No. 6, pp. 279–284. pl. 1).—This fungus is stated to be a facultative parasite, having been found encircling, attacking, and killing Benzoin astivale in contact with Alnus ineana, which also it had apparently killed. It is thought that the choking and consequent weakening effect of the encircling fungus may have had something to do with its increase of activity in the host. This is evidenced by the progressive diminution of growth of the latter above

the original point of attack (the parts below showing an increase of growth) during three years. A young red maple was also found to have been attacked in like manner and to have been killed above the point of contact.

Eelworm disease (Agr. Gaz. Tasmania, 22 (1914), No. 9, p. 3 $\{7\}$.—It is stated that the nematodes which infest clover also attack outs and several other cultivated besides many wild plants. They are carried on tools, wheels of vehicles, etc., as well as by animals, the eggs resisting desiceation for a long time.

It is claimed that turning the land as much as 5 in, deep destroys the nematodes, also that potassium sulphate applied to the land shortly before sowing the clover seed is safely protective to the plant during the short period of its susceptibility to nematode attack.

Maryland plant diseases in 1912, J. B. S. Norton (*Rpt. Md. State Hort. Soc., 15 (1912), pp. 182-188*).—After discussing the immediate and later effects of the very cold weather on plants in 1912 and stating that the cool moist summer was favorable to parasitic disease in Maryland, the author lists alphabetically about 50 plants with parasites observed in connection with each.

Report of the botanist, E. A. Bessey (*Michigan Sta. Rpt. 1914*, pp. 226, 227).—Besides brief notes of work regarding some plant diseases, more special mention is made of investigations by J. A. McClintock on Michigan giuseng troubles, particularly those due to nematodes. Golden seal was found susceptible to this pest.

The steam pan method of sterilization was found to give adequate protection against nematodes. A soil drench of formalin, I part to 100, prevented damping off in the beds, and black rot was controlled by a much higher concentration of this agent.

[Report on work in plant pathology] (New Mexico Sta, Rpt, 1914, pp. 80, 81).—The principal work carried on in the department of plant pathology has been the studies of the blighting of chili peppers, chlorosis of foliage of orchard trees, studies of diseases of apples, pears, and peaches, particularly the powdery mildew of the apple (Podosphara oxycanthar), and some truck crop diseases, one of which, Fusarium wilt, is said to cause considerable damage to tomato crops.

The blight of peppers is thought to be influenced by damp weather, as the disease spreads much more rapidly under such conditions than where the season is dry and free from heavy rains. So far no causative organism has been isolated.

In the studies on chlorosis of the foliage of orchard trees, plugging and spraying them with 1 per cent solution of ferrous sulphate were compared. The use of the material as a spray was found to benefit the trees greatly.

Notes, observations and minor investigations on plant diseases, H. S. Jackson (*Oregon Sta. Bien. Grop Pest and Hort. Rpl. 1913-14, pp. 261-283, figs. 15*).—Notes are given of observations and investigations on a considerable number of diseases of economic plants due to funci. etc.

Fungus diseases of Swedish melons and cucumbers, J. Eriksson (K. Landtbr, Akad, Handl. och Tidskr., 52 (1913), No. 4, pp. 233–253, figs. 9; Meddel. Centralanst. Försökv. Jordbruksområdet, No. 76 (1913), pp. 23, figs. 9).—The following fungi causing diseases are described and discussed in the paper: Cladosporium cucumcvinum, Cercospora melonis, and Colletotrichum lagenarium.

A contribution to the study of foot rot of cereals, P. Berthault (Rev. Gén. Bot., 25 bis (1914), pp. 29-34).—Reviewing reports and discussions of studies on this disease of cereals, and reporting on his own examination of diseased wheat stems sent in from several portions of France during 1913, the author states that while he did not find Leptosphæria herpotrichoides on these speci-

mens, Ophiobolus gruminis was abundant. Fusarium rubiginosum, it is claimed, is almost constantly present in this disease. It is thought that foot rot of cereals may be considered due to the attack of such fungi as Ophiobolus and Leptosphæria on the one hand and to various species of Fusarium on the other. Some discussion of the fructification of these fungi is also given.

Rust in the interior of graminaceous seeds, J. BEAUVIER (Rev. Gén. Bot., 25 bis (1914), pp. 11-27, figs. 10).—In continuation of work previously reported (E. S. R., 30, p. 241), the author states that within the seed coats of several wild or cultivated grains he has found the fruiting bodies and the mycelium of rusts. This occurrence is very frequent in certain species, as Puccinia glumarum in barley, and other rusts in Agropyron spp., Brachypodium pinnatum, etc. P. graminis is sometimes found in this relation on wheat.

Fungus diseases of cotton, L. Smith (Rpl. Agr. Expl. Sta. 81, Croix, 1912-13, pp. 59, 60).—It is stated that while the usual attacks of angular leaf spot, round spot, rust, and mildew of cotton are observed to do but little harm here, a much more serious case is that caused by a fungus which attacks young bolls almost to the time of their maturity. The trouble is thought to be due to a Macrosporium, possibly M. nigricantium, which is said to be associated with black rust of cotton in the United States.

A disease causing a blistered and torn appearance of young leaves and abortion and blackening of young flower buds is thought to be practically identical with that described by Cook (E. S. R., 29, p. 47) as causing a physiological disorder of cotton in the United States, differences in details as to manifestations being ascribed to differences in local conditions.

Spraying of peanuts for leaf rust (Agr. News [Barbados], 13 (1914), No. 328, p. 380).—Bordeaux mixture sprayed on twice (63 and 77 days after planting) under 80 lbs. pressure is considered to have given an increase of 42 per cent in the sprayed as compared with the unsprayed plat in the ease of the Gambia variety of peanuts affected with Urcdo arachidis.

Notes on miscellaneous potato diseases, F. D. Bailey (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 245-256, figs. 9).—Notes are given on investigations of various potato diseases in Oregon. Among these are several storage rots, the powdery dry rot due to Fusarium trichothecioides, dry rot due to F. caruleum, and jelly-end rot caused by F. orthocerus. Notes are also given on silver scurf, early blight, Verticillium wilt, mushroom root rot, and Rhizoclonia violacea, with suggestions for their control.

Brief accounts are also presented on the curly dwarf and internal browning of tubers due to nonparasitic causes.

Potato spraying experiments, F. D. Bailey (Oregon Sta. Bien. Crop Pest and Hort. Rpl. 1913-14, pp. 257-260, fig. 1).—Accounts are given of spraying experiments for the control of late blight of potatoes, which is said to be occasionally a serious menace in the western part of the State.

The results of the use of Bordeaux mixture and arsenate of lead for the control of this disease and insect pests show in one instance an increased yield of 44.4 per cent where no late blight was present. Experiments for two years in another locality showed that the late blight could be effectively controlled by Bordeaux mixture. When blight appeared a month before harvest, the yield was increased in one case 46 bu, per aere and in another 203 bu, when the plants were sprayed.

Leaf roll of potato, VIII, G. KÖCK, K. KORNAUTH. and O. Brož (*Ztschr.** *Landw. Versuchsw. Österr.*, 17 (1914), No. 5, pp. 270–300).—This continues recent reports on the study of potato leaf roll by the committee, as noted by these authors (E. S. R., 30, p. 243) and by Reitmair (E. S. R., 30, p. 48).

It is stated that this disease is associated with species of Fusarium in southern, and of Verticillium in northern, regions. The primary infection takes place from the soil, which, it is thought, may retain the fungus in an active condition for at least five years. Tubers from shoots not attacked on diseased plants will be sound, while those from infected shoots may be more or less permeated by the mycelium or may be simply weakened by its presence in the vascular system of the stolon. From an infected seed tuber the mycelium may (though apparently it seldom does) grow into the forming shoots (secondary infection), or the seed tuber may give rise to descendants which are simply weakened as an after-result of the disease. Resistance as regards varieties differs greatly, but no completely immune varieties are mentioned.

Control measures recommended include suspension of potato culture for at least five years on fields which have shown leaf roll; careful selection of seed, with particular reference to climate and soil; suitable fertilization of the soil to increase vigor in the crop; and careful elimination of plants showing leaf roll during growth.

A bibliography of contributions for 1913 is added.

Occurrence of silver scurf of potatoes in the Salt Lake Valley, Utah, P. J. O'GARA (Science, n. ser., 41 (1915), No. 1047, pp. 131, 132).—The author calls attention to the occurrence of silver scurf (Spondytocladium atrovirens) on potatoes in the Salt Lake Valley, Utah. From the investigation of the source from which the seed tubers were purchased, it is believed that this disease is widespread among the intermountain States, particularly in Utah and Idaho.

An endophytic endodermal fungus in Solanum tuberosum, E. M. Wilcox, G. K. K. Link, and Florence A. McCormick (Abs. in Science, u. ser., 41 (1915), No. 10\frac{1}{8}, p. 171).—A preliminary account is given of investigations on an endophytic fungus found in S. tuberosum. This fungus, it is said, may be found throughout the whole plant, but is confined to the endodermis. In the usual vegetative propagation of the potato if proceeds from the tuber throughout the shoots to the daughter tubers. The possible relation of this fungus to tuberization is discussed.

[Diseases of sugar cane on the island of St. Croix, 1913], L. Smith (Rpt. Agr. Expt. Sta. St. Croix, 1912-13, pp. 45, 46).—Marasmius sacchari is said to cause considerable damage to sugar cane all over the island. Fructifications have been reported from one plantation.

The chief remedies recommended include planting tops from land known to have been free from the disease for 8 or 10 years, the employment of Bordeaux mixture for soaking the cane tops 20 minutes before planting, and rotation, preferably with cotton followed by legumes or these with corn.

Red rot of the leaf sheath, which does some damage here, has been identified, it is said, with a fungus disease which is common in Java.

Effect of dilution upon the infectivity of the virus of the mosaic disease of tobacco, H. A. Allard (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 4, pp. 295–299).—Experiments are reported that were conducted with the idea of determining the effect of dilution upon the infective power of the virus of the mosaic disease of tobacco. A quantity of expressed sap from diseased leaves was passed through filter paper and all dilutions accurately determined, and inoculations immediately made from these to young vigorous tobacco plants growing in a greenhouse.

It was found that the virus of the mosaic disease, when diluted to 1 part in 1,000 of water, is quite as effective in producing infection as the original undiluted virus. It was observed that attenuation of the virus was indicated when dilutions of 1 part in 10,000 were made. At greater dilutions infection is not considered likely to occur. The author claims that the evidence at hand indi-

cates that there is something present in the virus of mosaic disease which is extraneous to the protoplasmic organization of healthy plants, and, in his opinion, parasitism offers by far the simplest and most reasonable explanation of its origin.

A fruit spot of tomato, R. Perotti and U. Cristofoletti (Staz. Sper. Agr. Hat., 47 (1914), No. 3, pp. 169-216, pls. 3, figs. 9).—Reporting a study of the fruit rot said to be peculiar to a small, pear shaped variety of tomato, the author states that this rot is associated with the presence of the fungus Cladosporium herbarum and of a bacterium described as a new species, Pseudomonas polycromigena, the latter being nonparasitic and apparently dependent upon the diminution of acidity in the fruit by its associated fungus.

Frequently the same spots show also the prescuce of another fungus, considered also as parasitic and described as a new variety, Oospora (Gidium) lactis solani. It is thought that C. herbarum is hindered by the presence of the other organisms, also that since not over 5 to 10 per cent of the fruits are attacked by C. herbarum, the development of a more resistant variety need not be very difficult.

Fruit pit studies in the Willamette Valley, C. I. Lewis (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 35-37, fig. 1).—The author reports three years' work conducted on a study of the fruit pit in the Willamette Valley, the disease being locally known under a number of names.

It is believed that the trouble may be due to some physiological disturbance, no definite cause having been determined for it. The general appearance of fruit affected by this trouble is indicated by spots, which may be only on the surface, and finally cause a depression in the skin, or the pits may not show on the outside, but be scattered throughout the flesh. Occasionally the trouble takes the form of a dry rot around the core.

The effect of various fertilizers on controlling this disease was investigated without conclusive results. The author comments on the effect of cold storage in retarding the disease.

Apple rust and die-back, H. M. NICHOLLS (Agr. Gas. Tasmania, 22 (1914), No. 9, pp. 351-360, figs. 6).—It is claimed that apple rust, cracking, die-back, and leaf spot, besides possibly other disorders of more or less obscure character, are due to the presence and activity of the fungus Coniothecium chomatosporium in some of its several stages or forms, which are briefly discussed.

It is stated that the activity of this fungus is favored by exposure to strong light, also by use of Bordeaux mixture, and that it is carried over winter largely on dead leaves, and spread probably by omitting to disinfect pruning tools between trees. Poor drainage also, it seems, may sometimes play a part, as may any condition tending to check normal growth of the trees.

No fungicidal preparations yet tested have proved entirely successful and safe.

Cedar rust on the apple, W. M. Scott (Rpt. Md. State Hort. Soc., 15 (1912), pp. 91-105).—This is a report with discussion on recent experience with apple rust, ascribed mainly to Gymnosporangium macropus, though it is thought to be producible also by G. globosum and G. clavipes.

Destruction of all cedars in the locality is the remedy most favored. When this is not practicable the use of such a fungicide as lime sulphur is found helpful. This is to be applied just before the blossoms open, again as soon as the petals fall, and twice later at intervals of about 10 days. There is also a discussion of resistant apple varieties.

Bacterial gummosis or bacterial canker of cherries, H. P. Barss (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 224-240, figs. 7).—A progress report is given of an investigation previously noted (E. S. R., 20, p. 154).

The bacteria causing the disease have been isolated and artificial inoculations made which indicate that they are the cause of the trouble in question. Some varieties were found to be naturally immune, and the planting of such is advised. There appear to be two slightly different kinds of bacteria concerned in this trouble, and in addition to blighted buds and spurs, cankers are formed on the branches, limbs, and trunks of trees.

The method of dissemination of the trouble is unknown, but indications point to the possibility of sucking insects being among the carriers of the bacteria. The most serious infection is believed to take place in the autumn, the new infection developing slowly at first, and late in winter and early in spring becoming of very rapid growth. Wound parasites and wood rotting fungi frequently enter at the cankered spots and extend the injury originally caused by the bacteria.

A similar canker disease has been found on prunes, peaches, and apricots, and pathogenic bacteria apparently identical with the organisms found on cherry trees were isolated.

Suggestions are given for the control of the disease, which include the planting of resistant stocks to be later grafted to commercial varieties, and cutting out of all diseased material.

Experimental spraying of prunes for control of brown rot, F. D. BAILEY (Oregon Stu. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 241-244).—The results of spraying experiments carried on in 1913 and 1914 for the control of the brown rot of stone fruits are given.

In 1913 four spray mixtures were tested, Bordeaux mixture, Burgundy mixture, self-boiled lime sulphur, and commercial lime sulphur. Two applications were given of all except the Burgundy mixture. The results seemed to indicate that for the earlier attack Bordeaux mixture gave the best results, while the second record showed a greater loss than with the check in all cases except where self-boiled lime sulphur was employed.

In 1914 the work was repeated, and comparing the results obtained both seasons it is considered probable that Bordeaux mixture will be found as satisfactory as any spray for the control of this disease. The best time of application of the fungicides was found to vary with conditions that are not clearly understood.

A Pacific Coast rust attacking pear, quince, etc., H. S. Jackson (Oregon Sta. Bien. Grop Pest and Hort. Rpt. 1913-14, pp. 204-212, figs. 3).—This is a detailed account of the attack of Gymnosporangium blasdalcanum on quinces, pears, etc., a preliminary notice of which has already been given (E. S. R., 32, p. 51).

A bibliography is given.

Varietal resistance of the gooseberry against mildew and the effects of sulphur treatment therefor, G. Köck (*Ztschr. Landw. Versuchsw. Österr., 17* (1914), No. 6-7, pp. 634-637).—Of about 100 varieties of gooseberry tested, about 16 proved to be susceptible to American gooseberry mildew, while 56 proved to be susceptible to injury from treatment with powdered sulphur for the prevention of the disease.

Fungus diseases of coffee in Porto Rico, G. L. Fawcett (Porto Rico Sta. Bul. 17 (1915), pp. 29, pls. 8).—A discussion is given of the commoner and more destructive diseases of coffee in Porto Rico, among which are the leaf rot or thread blight due to Pellicularia koleroya, the leaf spot caused by Stilbella flavida, root diseases due to Rosellinia sp. and Dematophora sp., and berry spot caused by Cercospora coffeicola. These diseases are described at considerable length and the results of investigations for their control are given.

In addition to the above, notes are given on leaf spot due to *Cephalosporium* sp., a root and trunk disease associated with the presence of *Fusarium* sp., and the attack of nematodes (*Heterodera radicicola*).

For the leaf rot no satisfactory method of control has been found, although spraying with Bordeaux mixture will lessen the disease to a considerable extent. For the leaf spot Bordeaux mixture is usually found quite effective if thoroughly applied. For the control of the spot on berries the author recommends providing adequate shade, as this not only renders the action of the fungus less harmful, but also improve the quality of the coffee. For the root diseases ditching about the trees, together with the use of unslaked lime, sulphur, or other substances about them is recommended.

Black root disease of limes (Agr. News [Barbados], 13 (1914), No. 327, pp. 364, 365).—This is the mycologist's report, continuing observations of South (E. S. R., 26, p. 245; 28, p. 149), on Rosellinia bunodes attacking lime trees in Dominica.

This important disease is said to be different from one somewhat similar on cacao. It appears only on estates with fairly recent forest clearings, apparently preferring trees growing under very good conditions. New roots which often appear above the wound on the collar may remain healthy for a time and lead to partial recovery of the tree. The fungus remains active on roots and branches in the soil, attacking new roots and following these to the collar, and extending up the tree if dampness and shade are abundant.

Spores of two forms occur on the above-ground portions (the later form being the more resistant), but it is thought that infection usually occurs by contact of live portions with dead roots bearing the fungus.

The wet weather of the year is thought to account in part only for the seriousness of the situation, the natural spread of the roots playing an important part.

Remedial measures suggested include the use of carbon bisulphid emulsion as advocated by Bordaz (E. S. R., 31, p. 549), isolation by means of trenches, ventilation, destruction by fire of all affected wood, and budding on sour orange, which is said to be immune to this fungus.

Black knot of birch, G. MASSEE (Roy. Bot. Gard. Kew, Bul. Mise. Inform. No. 9 (1914), pp. 322, 323, fig. 1).—It is stated that Plowrightia virgultorum is the cause of a disease found on birch trees in parts of Scotland. England, Sweden, Switzerland, Finland, and Germany. The disease is described in its several stages.

Removal of infected branches is the only remedy suggested.

The relationship of Endothia parasitica and related species to the tannin content of the host plants, M. T. Cook and G. W. Wilson (Abs. in Science, n. ser., 41 (1915), No. 1048, pp. 171, 172).—Two strains of E. parasitica (one American and the other Chinese). E. radicalis, and E. radicalis mississippicasis were grown in culture media to which different percentages of commercial tannin and special extracts were added.

The results of the experiments indicate that the commercial tannins are variable and probably not pure tannin; that ordinary commercial tannin and pure tannin extracts are not the same; and that the form or quantity of tannin or tannin-like substances with which the fungus comes in contact in the host plant is not known. The food supply influences the vigor of the fungus and its power of resistance. High percentages of tannin usually cause a retardation of germination, frequently followed by an abnormal growth of aerial mycelium. E. radicalis mississippicusis was found most resistant, E. parasitica second, and E. radicalis third, and the American strain of E. parasitica was more resistant than the Chinese strain.

E. parasitica may feed to some extent on tannin. Specially prepared pure tannin extracts were less toxic to the fungus than the commercial tannin. Coloring materials which are usually estimated as tannins were toxic. Tannic acid is toxic to many parasitic fungi, but there are other compounds associated with it that are more toxic and may be more important in the economy of the host plant.

A new filbert disease in Oregon, H. P. Barss (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913–14, pp. 213–223, figs. 9).—A description is given of a serious filbert disease, which is said to be prevalent in western Oregon, that is characterized by the blighting of the buds and new shoots, spotting of the leaves, girdling and breaking down of smaller branches, and the formation of cankers on the larger branches and trunks. Bacteria have been associated with this disease, but while they are believed to cause it inoculation experiments have not completely demonstrated the relation that they bear to the trouble. Certain varieties of filberts were found more resistant to the disease than others, and for prevention and control the author recommends the growing of filberts in tree form, selecting resistant varieties, and spraying throughout the spring to reduce the number of infections.

Report on cultures with foliaceous species of Peridermium on pine made in 1914, G. G. Hedgock and W. H. Long (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 171).—A summary is given of experiments with P. acicolum, P. carneum, P. delicatulum, P. inconspicuum, P. intermedium, and P. montanum, all taken from species of pine. A total of 712 inoculations were made with these species, and with the species of Coleosporium with which they were associated as alternate forms.

The results of the experiments indicate that at least four of these species and the related species of Coleosporium belong to a single polymorphic species, and that the transfer from one herbaceous host to another is accomplished through the ecial forms in the pines.

Injury by disinfectants to seeds and roots in sandy soils, C. Hartley (U, S, Dept. Agr. Bul. 169 (1915), pp. 35, pl. 1. figs. 2).—The results of several seasons' investigations on the control of damping-off of pine seedlings are given, a preliminary report of which has already been noted <math>(E, S, R, 31, p, 647).

The author found that sulphuric, hydrochloric, and nitric acids, and copper sulphate used in disinfection of seed-bed soil caused injury to the roots of pine seedlings and prevented the development of many species of weeds. Many of the injured seedlings later resumed root growth and recovered. The injury is considered due to the concentration of the disinfectant in the surface soil, due to the capillary rise of the soil solution and the evaporation of water from the soil surface.

It was found in a sandy soil that all injury could be prevented by frequent watering during a germinating period. It could also be prevented by an addition of lime shortly after treating the soil with disinfectant. The use of lime, while undesirable in the case of growing pine seedlings, is believed to be the only way in which injury to angiospermous seedlings can be prevented. Acids also, it was found, could be applied to seed beds at the time of sowing without injury to dormant pine seed. Formaldehyde and corrosive sublimate solution in sufficient strength for disinfection should be used several days before sowing the seed, as they are liable to kill dormant pine seed in the soil. Formaldehyde applied at or before seed sowing was never found to cause the injury to germinating pine seed that was caused by acids and salts,

ECONOMIC ZOOLOGY-ENTOMOLOGY.

Extermination of ground squirrels, gophers, and prairie dogs in North Dakota, W. B. Bell and S. E. Piper (North Dakota Sta. Circ. 4 (1915), pp. 11, figs. 6).—It is estimated that the annual loss to farmers in North Dakota from the depredations of six species of rodents amounts to more than a million dollars, and in dry years this loss is probably more than doubled. The Richardson ground squirrel or flickertail, commonly called "gopher" in the State, is the most conspicuous offender.

In January, 1914, an investigation was started by the station in cooperation with the Biological Survey of this Department, the field work commencing early in April and continuing into September. It was found that the Richardson ground squirrel, like the California ground squirrel, is killed more readily by strychnin absorbed through the cheek pouches from properly prepared strychnin-coated grain than through the stomach, only one-fifth as much poison being required to kill when thus taken directly into the circulation. The authors give directions for the preparation of a formula which has given excellent results in exterminating the Richardson ground squirrel, and state that it is equally as effective in destroying the Franklin or gray ground squirrel and the striped or thirteen-lined ground squirrel. In tests made the average cost of treating 1,528 burrows in 135 acres, including poison, grain, and labor, was slightly over 24 cts. per acre.

Methods of destroying prairie dogs and pocket gophers are also briefly described.

Preliminary census of birds of the United States, W. W. COOKE (U. S. Dept. Agr. Bul. 187 (1915), pp. 11, fig. 1).—This is a report of work carried on during the summer of 1914 for the purpose of ascertaining approximately the number and relative abundance of the different species of birds occurring in this country. Such information has been found necessary in administering the federal law relating to the protection of migratory game and insectivorous birds as a basis for determining the adequacy of the protection now afforded them. Nearly 200 reports were received from observers, mainly from the section of the United States north of North Carolina and east of Kansas.

"The census covered 58 of the 108 acres of the average farm of the Northeastern States and revealed on this area a bird population of 69 nesting pairs, and on the remaining 50 acres it is estimated that there would be about one pair to the acre; in all, 114 nesting pairs to the 108 acres of farmed land. On the 46 acres of wild land existing for each 108 acres of farmed land it is safe to assume that there would be fewer birds than on the census-covered area.

"The results of the census show that the numbers of birds are too few, and it is believed that with adequate protection and encouragement they can be materially increased. The record for density comes from Chevy Chase, Md., where 161 pairs of 34 species were found nesting on 23 acres.

"This preliminary census shows that the most abundant bird on farms of the Northeastern States is the robin; that the next is the English sparrow; and that following these are the catbird, the brown thrasher, the house wren, the kingbird, and the bluebird in the order named."

Some common birds useful to the farmer, F. E. L. Beal (U. S. Dept. Agr., Farmers' Bul. 630 (1915), pp. 27, figs. 23).—Brief popular accounts of the more important birds of the farm, particularly as relates to their food habits.

Food of the robins and bluebirds of the United States, F. E. L. Beal (U, S, Dept, Agr, Bul, 171 (1915), pp, 31, figs, 2).—This bulletin presents in detail the results of investigations of the food of five species of American robins and blue-

birds. The species of insects and other animal and vegetable substances taken from the stomachs of a large number of individuals have been identified and are listed for each of these species.

Summarizing the results of studies of the common robin (Planesticus migratorius and subspecies), the author concludes that while in all probability it is to-day doing much more good than harm it must be acknowledged that the bird is potentially harmful since its diet contains a large percentage of fruit, including many varieties. Investigations of the varied thrush, or Ovegon robin (Ixoreus navius and subspecies) indicate that it is not likely to do much mischief by eating useful insects since a good proportion of its animal food consists of such as are of no economic significance. Since this bird does not at present spend the breeding season in a well settled and cultivated country farm products are not fed upon. The eastern bluebird (Sialia sialis and subspecies) does not prey upon any product of husbandry or in any way render itself in jurious or annoying. During the spring and early summer when small fruits are at their best it subsists on insects to the extent of five-sixths of its food, and during the late fall and early spring when insects are scarce only waste fruit is available. The western bluebird (8, mexicana subspecies) is found to be an eminently useful species. The mountain bluebird (8. currucoides) has probably not yet come in contact with the products of husbandry extensively enough to demonstrate its real propensities, but the nature of its food does not indicate that there is much to be feared from it.

Quassiin as a contact insecticide, W. B. Parker (U. S. Dept. Agr. Bul. 165 (1914), pp. 8, fig. 1).—Quassia wood (Pierasma excelsa), a native of Jamaica that is available in considerable quantities, has for many years been employed in the preparation of spray solutions for the control of the hop aphis (Phorodon humuli). The percentage present of quassiin, the active principal in the chips, varies somewhat and does not appear to be definitely known. If the percentage be 0.75, as given by one author, in order to use it at an effective rate of 0.4 gm. to 2,000 cc., only 1.5 lbs. of chips to 100 gal, of spray would be required. The author states that if twice the amount of chips calculated to be necessary were used, in order to be on the safe side, and 3 lbs. of whale-oil soap added, the cost of material for 100 gal, of the spray would amount to but 24 cts.

In an attempt to determine its insecticidal value the author compared the action of quassin with that of a standard contact insecticide, namely, nicotin sulphate solution, standardized to 40 per cent, and used at the rate of 1:2,000. Since whale-oil soap even at the greatest dilution at which it has any spreading effect was found to kill a certain percentage of aphidids, a soap bark solution was used at the rate of 2 lbs. to 100 gal. of water. In conducting the experiments prune twigs infested by the hop aphis (*P. humuli*) and the prune aphis (*Hyalopterus pruni*) were brought from the field and after being sprayed with the solutions were set in moist sand. The results presented in tabular form show that "quassiin used at the rate of 0.4 gm. to 2,000 cc., or 6.5 oz. of 40 per cent solution to 100 gal., was almost as effective against the hop aphis and the prune aphis as nicotin sulphate, 0.4 gm. to 2,000 cc., is fully as effective."

The author is of the opinion that quassiin has possibilities as a commercial insecticide and that it can be cheaply prepared and profitably sold at a lower price than some of the materials that are now on the market. It is pointed out, however, that the experiments were conducted under conditions existing at Sacramento, Cal., and that the efficacy of this insecticide should be determined also for a more humid climate before a commercial recommendation is made,

Para-dichlorobenzene as an insect fumigant, A. B. Duckett (U. S. Dept. Agr. Bul. 167 (1915), pp. 7, pls. 2).—Para-dichlorobenzene is a colorless, crystalline substance that volatifizes very readily as a colorless vapor with a peculiar ether-like odor, and which has been known for many years but only recently used as an insecticide. The vapor is harmless to man and domestic animals under ordinary conditions, but in many instances it is a specific poison for insects. The greatest advantages which it possesses are absolute noninflammability and its comparatively low cost, and the disappearance of the etherlike smell upon exposure of the fumigated substances to the open air. It is stated that it can be used in closed or occasionally opened cupboards and even in sitting rooms without causing any inconvenience whatsoever. Fumigation experiments with stored product insects conducted during the spring of 1914. here reported in tabular form, show it to have destroyed all of ten species of beetles exposed when used at the rate of 2 lbs. to 100 cu. ft, of space at a warm temperature but only 70 per cent were killed when exposed at a low temperature. Flies and aphidids were destroyed when it was used at the rate of S oz. to 100 cn, ft. of space.

The author concludes from the observations and experiments that paradichlorobenzene is an excellent fundigant against stored product insects, case-bearing clothes moths, roaches and ants, museum pests, and miscellaneous house insects. It is also an effective substitute for potasium cyanid in collecting bottles.

An account of the chemical and physical properties of this chemical, prepared by the Insecticide and Fungicide Laboratory, is appended.

A method of fumigating seed, E. R. Sasseer and L. A. Hawkins (U. S. Dept. Agr. Bul. 186 (1915), pp. 6, figs. 2).—The need of a reliable method for destroying insects present in seeds imported into this country, without injury to the seed, led the authors to conduct experiments with a vacuum chamber into which some gaseous insecticide could be introduced. The construction of the apparatus devised, which consists of a fumigation chamber of iron tubing 36 in. long by 12 in. in diameter and an air pump, is described. The air pump, driven by a motor and capable of reducing the air pressure to the equivalent of about 0.05 mm, of mercury, is used to secure an almost complete vacuum of the fumigation chamber, which is fitted with a vacuum gauge, etc.

The results of the experiment in which hydrocyanic acid gas was introduced into an air-tight chamber from which the air had been practically exhausted, here presented in tabular form, show the method to be effective for various seeds, insects, and conditions. In an experiment with ten avocado seeds infested with larvae of *Conotrachelus* sp. and the broad nosed grain weevil in all stages, an exposure of gas generated from 4 gm. of sodium cyanid for one-fourth hour was effective, fifty insects of different stages having been killed and all the seeds having germinated. Two gm. of sodium cyanid were effective when the exposure was increased to one-half hour.

It is stated that further experiments with special reference to the use of carbon bisulphid will be conducted.

Report of the entomologist, R. H. Pettit (Michigan Sta. Rpt. 1914, pp. 232, 233).—A brief statement of the work of the year including the occurrence of several insect pests of considerable economic importance.

The carrot rust fly (*Psila rosa*) appears to have become established at Sault Sainte Marie where it injured a small area of table carrots in 1913. It is pointed out that in addition to carrots it attacks celery, parsnips, and perhaps other vegetables, and that in Europe it has proved to be a difficult pest to control. The clover snout beetle (*Sitones hispidulus*) is reported to have been

the source of considerable injury to alfalfa, and two species of apple red bugs were found in considerable numbers. The occurrence of a snout beetle (Anametris grisca) on apple for the first time in Michigan, a tree hopper (Ceresa) in young apple orchards where it killed the twigs, and the clover seed caterpillar (Enarmonia interstinctana) which injured June clover heads in a restricted area after a rest of some 20 years, is reported.

Report of the department of entomology (Oregon Sta. Bien. Crop Pest and Hort. Rpt. 1913-14, pp. 95-202, figs. 98).—This second report, prepared under the Crop Pest and Horticultural Law of 1911 (E. S. R., 29, p. 158) contains a statement of the investigations carried on during the years 1913 and 1914, and summarized accounts of important insect pests, including the nature of their injury, life history and habits so far as known, technical description, methods of control, and references to the literature thereon.

The insects thus discussed are the fruit (ree leaf Syneta (Syneta atbida) and the eye-spotted bud moth by H. F. Wilson and G. F. Moznette: the fruit tree leaf roller (Archips argyrospila), the peach twig moth (or peach and prune twig borer), an apple leaf miner (Phytlonorycter (Lithocolletes) cratagella), a new cherry pest (Simplemphytus pacificus), injurious gall mites [the pearleaf blister mite, the grape leaf mite (Eriophyes vitis), the walnut leaf mite (E. tristratus crinea), and the filbert bud mite (E. avellena), insect pests of stored products [the Indian meal moth and the saw-toothed grain beetle (Silvanus surinamensis)], the thistle butterfly (Yanessa cardui), grasshoppers in Oregon, insecticide investigations of 1914, and minor insect pests [the Prionus beetle (Prionus californicus), the bud weevils (Sciopithes obscurus, Paraptochus scllatus, and Thricologis inornata), the bud click beetle (Limonius discoideus), the blossom fly (Bibio nervosus), a peculiar undetermined apple insect which mines under the skin, the black cherry aphis (Aphis cerasi) on nursery stock, two apple and pear membracids (Stictocephala incrmis and Cerasa basatis), and the spotted Diabrotica (D. soror) as a fruit pest], by H. F. Wilson; the variegated cutworm, and the olive green cutworm (Dargida procinctus), the rose curculio (Rhynchites bicolor), injuring blackberry buds, the radish weevil—a new pest (Cleonus sparsus), clover seed injured by midge (Dasyncura leguminicola), nematode gall worms or eelworms (Heterodera radicicola), tipulid work in prune wood (Ctenophora augustipennis), and fomato worms, by A. L. Lovett; the antique or rusty tussock moth (Notolophus antiqua), by L. G. Gentner; the brown lace-wing (Hemorobius pacificus), by G. F. Moznette; the alfalfa looper (Plusia californica) as a truck crop pest, by L. Childs; and the rose leaf hopper as a fruit pest $(Empoa\ ros w)$, by H. F. Wilson and L. Childs.

The fruit tree leaf Syneta, which has never been recorded outside the Pacific Northwest, is the source of considerable injury to fruit trees, including the apple, pear, cherry, prune, etc., through the feeding of the larvæ upon the fibrous roots and the adults upon the flowers, foliage, and fruits. It is stated that cultural methods are not at the present time of any avail and that spraying thus far has not been found profitable in its control. Spraying experiments conducted against the bud moth led to the conclusion that oil sprays as ordinarily used are not effective. The fruit tree leaf roller is said to be found quite generally throughout the Willamette Valley. Investigations have led to the recommendation that a 10 per cent crude oil emulsion be applied about the time the buds are opening, or earlier if the eggs are found to be hatching earlier. Should the oil fail to kill the eggs, an application of arsenate of lead 2:50 should be made just before the blossoms open. The apple leaf miner is said to be quite common throughout the orchards of western Oregon, though not serious enough at the present time to warrant special applications of spray.

A new sawify (8, pacificus), first observed in the winter of 1913, is reported to be the source of some damage to cherry trees. The larve of the radish weevil (C, sparsus) tunnel about Inside the radish, devouring the whole interior of a small plant, and rendering it unfit for food. Tipulid larve (C, angustipennis) were observed tunneling in the decayed wood of prune trees in an orchard near Corvallis, and the injury, while secondary in nature, is said to be fairly serious since it shortens the life of the infested trees.

Tomato insects, root knot, and "white mold," J. R. Watson (Florida Sta. Bul. 125 (1914), pp. 55-78, figs. 14).—A brief popular account is given of the more important insect enemies of tomatoes in Florida and of root knot and white mold and means for their control.

Three cornered alfalfa hopper, V. L. Wildermuth (I. S. Depl. Agr., Jour. Agr. Research, 3 (1915), No. 4, pp. 343–362, fig. 1).—This membracid (Stietocophala festina), first described in 1831 by Say, has become of economic importance to alfalfa crops in the irrigated valleys of the southwestern United States and to alfalfa and cowpeas in the Southern States. Injury is due to the sucking of plant juices by both adults and the larvae and the development of a feeding scar which often takes the form of a ring or girdle and which is usually accompanied by a gall formation.

In this paper the author deals with its specific identity, distribution, and food plants; presents descriptions of its several stages; and reports studies of its life history and habits, seasonal history, damage to alfalfa and other plants, natural enemies, and preventive measures.

"Plants of the legume family constitute the favorite food. The eggs are deposited in the stems of the food plants, usually back of the sheath leaves or below the surface of the ground. In cowpeas the eggs are deposited in pockets on the stems. The egg period in Arizona occupies from 12 to 41 days and the five stages of the nymphal period from 22 to 69 days. The average combined length for both periods is about 50 days. In southern Arizona there are four generations annually and during extremely mild winters the adult insects are active throughout the season. During colder winter the species hibernates in both the egg and adult stages.

"The alfalfa hopper is little affected by natural enemies and is only reduced in numbers by the variable winter temperatures. The Sonoran redwing [Agelaius phæniceus marginella] was found to feed upon the species. The cleaning up of places of hibernation and the eradication of weeds, rubbish, etc., is the only known system that will reduce the numbers of the pest."

A bibliography of 11 titles is included.

Control of green pea aphis in 1914 (Macrosiphum pisi), L. B. Smith (Virginia Truck Sta. Bul. 13 (1914), pp. 301–312, fig. 1).—This is a report of experiments with control measures for one of the most troublesome and destructive insects with which truck growers in tidewater Virginia have had to contend. The results of spraying experiments lead the author to recommend the use of either of the following formulas: Blackleaf 40 10 oz., whale-oil soap 4 lbs., and water 50 gal.; or whale-oil soap 5 lbs. and water 50 gal. The spray should be applied within one or two days after the aphidids are found on the pea vines and two or three sprayings may be necessary especially if the aphidids are very numerous. The second spraying should come about one week after the first. The growing of clover, especially crimson clover, in the vicinity of the pea field should be avoided if possible since this species passes approximately eight months of the year on clover.

The life history and habits of the corn earworm (Chloridea obsoleta), H. GARMAN and H. H. JEWETT (Kentucky Sta. Bul. 187 (1914), pp. 513-591, pls. 13, figs. 3).—Observations of the bollworm or corn earworm in Kentucky were

commenced by the senior author in 1889 in which year it was very common and has since remained so. It is not as common in some seasons as it is in others; it may be difficult to find in a locality one summer and appear in very great numbers in another. In 1893 it was observed working on tobacco and has since been found constantly present where tobacco is grown next to corn. The authors' observations indicate that tomatoes are not the favorite food, but that the worms feed upon them when corn becomes too ripe or none is to be found.

In 1907 plantings of several widely different varieties of corn, including field and table varieties, were made with the view of determining its preference, if any, and the time at which corn is most subject to injury. The results which are presented in tabular form show an increase in the injury with the advance of the season, the early plantings, without regard to variety, generally showing less injury than those planted later.

"Sirup baits constantly used with a view to showing when the moths were abroad in the field failed to attract a single one. Electric lanterns of excellent quality also failed to attract the moths though kept in some cases in the midst Larvæ of the second brood were secured in August, and on the twelfth to the nineteenth of the month left the corn for pupation. Adults from these pupe emerged in early September (August 28 to September 9) in confined examples, and on the eleventh eggs were found attached to the silks. Larvæ hatched from some of these eggs September 14, and pupated October 17. Adults of one or another broad were abroad during all this period, apparently. On September 11 eggs were found attached to silks. On October 9 . . . corn planted August 5 was found to have eggs on every ear, sometimes six or eight on the silks, occasionally one at the edge of the busks. They were noted as abundant again on the nineteenth and twenty-second. On the twenty-fourth they were noted as hatching, and individuals of the brood were confined and followed to maturity." A record is given of 165 moths reared in the laboratory from eggs that were laid from September 7 to 11, the first adults emerging on September 28 of the same year and the last on August 14 of the following Rearings showed that the minimum time required for complete development from egg to adult was about one month and three or four days. "The fact is patent that the corn earworm begins its injuries in the spring as soon as it finds suitable food and continues producing broads at the rate of about one a month until severe frost destroys its food again in the fall."

"Taking the average period of a brood as about 32 days, from egg laying to egg laying, and beginning with the brood represented by the example secured June 13 and emerging July 11, ending with that reared in September and October, it appears that three broods developed as follows: (Brood 1) egg about June 10, pupa June 26, adult July 11; (Brood 2) egg July 13, pupa July 28, adult August 12; (Brood 3) egg August 14, pupa August 29, adult September 12; (Brood 4) egg November 3. Brood imperfect owing to frost."

Observations made in 1913 at Hickman, the only region in which cotton is grown in Kentucky, are reported. The life periods as observed in 1913 are detailed in tabular form. In observations made in November, 1911, in plats planted in corn, pupe were taken from the soil at depths varying from 1 to 7 in, and at distances from the nearest corn stalk varying from 4 in, to 2 ft. 4 in.

Tests of the value of arsenate of lead paste and powder in 1914 in the control of the pest on corn failed to justify the expense involved. Mention is made of a bacterial disease observed in the fall of 1911.

Biological notes are presented upon seven different insect enemies observed during the course of the work. *Trichogramma pretiosa* parasitized 81 of 1,661 bollworm eggs collected in 1913. The larva of a telephorid beetle, perhaps

Chauliognathus marginatus, is said to follow the worms into their burrows and during some seasons devour large numbers of them. The common lady beetle Megilla maculata of which there are at least three broods during the season in Kentucky is said to be a constant frequenter of corn where it feeds upon the egg. Records of the rearing of three broads in the insectary are detailed in tabular form. Hinnodamia convergens frequents corn silk and feeds upon the eggs of the bollworm, at Hickman it having been found on corn in about equal numbers with M. maculala. A true bug, Coviscus ferus, of which two broads were reared in the insectary, is said to have proved to be a useful check in the increase of the pest. The insidious flower bug (Triphleps insidiosus), while appearing to feed to some extent on plant juices, is common among corn silk and is very useful because of its destruction of the egg. It was found to oviposit in the tender corn silk and rearing studies reported show four molts to occur before it reaches maturity. The average time passed in development of the eggs to maturity was 15 days, 31 hours. The lace-wing fly Chrysopa oculata, a common enemy, was reared through three broods in 1912, the number of eggs deposited by a single individual varying from 27 to 56.

The illustrations include colored plates which show the color variations of the adult and larva. A monograph of this pest by Quaintance and Brues of this Department has been previously noted (E. S. R., 17, p. 160).

[Codling moth investigations], F. Garcia (New Mexico Sta. Rpt. 1914, pp. 67-71, figs. 3).—Experiments conducted to determine the attractivity of electric lights of various colors placed in the orchard brought out the fact that a large proportion of the first brood of moths, developing from wintered-over larve, are either males or infertile females. Charts are given which show the time of emergence of the maximum number of wintered-over codling moths, irregularity of emergence of the larve of the different broods, and the time at which the larger number of larve occurred. The results of spraying work, based upon a life history study, as shown in tabular form, is thought to have been very satisfactory.

The European pine shoot moth; a serious menace to pine timber in America, Λ. Busck (U. S. Dept. Agr. Bul. 170 (1915), pp. 11, pls. 6).—This is a more detailed account of Evetria buoliana than that previously noted (E. S. R., 32, p. 251).

The author deals with the history of the species in Europe, food plants, introduction and distribution in America, life history, character of injury, description of the several stages, allied American species, natural enemies, and method of control. Survey investigations made during the summer of 1914 have established the fact that the species has been repeatedly introduced on European nursery stock and that it has become established in nurseries and parks in several localities scattered over pine States, namely, Massachusetts, Connecticut, Rhode Island, New York, New Jersey, Pennsylvania, West Virginia. Ohio, and Hlinois. It is stated that in none of these localities, except on Long Island, has the species existed for more than the last two years, and in most of them it has become established only within the last year. As yet the pest has been found only in nurseries and private parks supplied by these infested nurseries. case has it yet been found on forest trees in America. It is confined to pine and does not attack other coniferous trees. It is pointed out that the species attacks mainly young trees between 6 and 15 years of age, but it is often excessively destructive to younger plantings and seedlings and injurious also to older trees, though trees of 30 years or older are rarely seriously affected.

The full life history of the species in America has not been ascertained. While in the main it is the same as in Europe, a very distinct difference has

already been noticed, due to the longer and warmer summer and fall in this country. The author expresses the opinion that at the present time it is possible to eradicate the pest from this country.

A list of literature relating to the subject, consisting of 13 titles, is appended. The Mediterranean fruit fly in Bermuda, E. A. Back (U. 8. Dept. Agr. But. 161 (1914), pp. 8).—This paper, based upon an investigation made by the author in Bermuda during December, 1913, discusses the history of the fruit fly in Bermuda, its life history, host fruits, and the possibility of eradicating it from those islands.

For nearly fifty years the peach industry of Bermuda has been ruined by this pest, which is thought to have gained entrance in 1865 in a cargo of fruit from the Mediterranean region bound for New York which storms forced to discharge there. Since that time it has spread over the islands, which consist of 19½ square miles of rolling country, and has long since ruined the excellent peach industry enjoyed by Bermuda in the early days and caused such discouragement among prospective fruit growers that at the present time native-grown fruit in Bermuda is a luxury. To the 47 fruits listed by Winter in the bulletin previously noted (E. S. R., 29, p. 656) as attacked by the Mediterranean fruit fly in Bermuda, the author adds the ball kamani (Calophyllum inophyllum), the prickly pear (Opuntia sp.), and the acordia.

It is stated that while at the present time Bermuda is probably a source of comparatively small danger to the United States as a source of infestation by this pest, both on account of trade relations and the climatic conditions surrounding New York, its extermination in these islands will be decidedly to the advantage of both Bermuda and the United States. It is pointed out that the topography of these islands is such that they can be easily inspected; that the trees and shrubs, the fruits of which are subject to infestation, are comparatively few numerically; and that a large proportion of the uncultivated land supports little that is subject to attack. Experience in all countries where clean cultural work has been undertaken, but especially in the city of Honolulu, has shown that no lasting beneficial results will follow such work as has been carried on in Bermuda unless extermination is the object in view. "The value of the fruit grown in Bermuda is not sufficient to warrant work being carried on with any other object. In no country where the fly now exists could work of extermination be undertaken with such assurances of success as in Bermuda. If clean cultural work were supported continuously by adequate legislation and undertaken by a person sufficiently conversant with the problem and eager to make a unique record in the entomological world, the Mediterranean fruit fly could be exterminated from Bermuda within three years, without the expenditure of a prohibitive amount of money."

Susceptibility of citrus fruits to the attack of the Mediterranean fruit fly, E. A. Back and C. E. Pemberton (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 4, pp. 311-330, pls. 3, figs. 3).—The authors here report the results of investigations conducted in the Hawaiian Islands which tend to show that even if Ceratitis capitata should obtain a foothold in the warmer portions of the United States, it probably would not be the serious pest to fruit that previously published literature would indicate. The paper includes a historical review and discussion of host fruits, habits of the fly, proportion of egg punctures containing eggs, mortality of eggs and larvæ, persistent attack leading to infestation of the pulp, secondary attack of citrus fruits by insects other than the fruit fly and by fungi, and effect of attack of the Mediterranean fruit fly upon citrus crops of California and Florida.

The authors point out that citrus fruits are not the favored host fruits of *C. capitata* that the earlier writers thought. "While grapefruit, oranges, lemons, and many limes may become quite hadly infested with well-grown larvae if allowed to remain on the free long after they become sufficiently ripe for the market, nature has so well equipped them to withstand attack that larvae are seldom found in their pulp until they are much overripe. Oranges and grapefruit are generally eaten and found uninfested if gathered as they ripen." The oil of the cells ruptured in the formation of the egg cavities kills a large percentage of the eggs and newly-hatched larvae. "Larvae that succeed in entering the rag from the egg cavity are able to reach the pulp in astonishingly small numbers because of the imperviousness of the rag. It is only the persistent attack of successive lots of larvae hatching from different batches of eggs laid in the same puncture in which the oil has become inoperative that finally breaks down the barrier between the young larvae and the pulp.

"The Mediterranean fruit fly is quickly affected by low temperatures. A temperature of about 56° F, has lengthened the time required by the fly to pass from the egg to the adult stage from 14½ to 91 days. A temperature ranging from 50 to 55° will either seriously check development or kill large numbers of the immature stages of the fly. The winter mouthly mean temperatures of California and Florida are so similar to those of the citrus regions of southern Spain and Italy and of Sicily that it is to be expected that the fruit fly if introduced to the mainland would not become a serious pest to Citrus spp. It happens that the very cold temperature necessary to bring citrus crops to that degree of perfection in which they are most susceptible to fruit fly attack likewise renders the fly so inactive or sluggish that it may be disregarded as a pest for that period of the year.

"In addition to the assistance of adverse climatic conditions during that part of the year when they are most needed to protect citrus crops, the growers of California and Florida are still further protected—and most admirably so—from attack by the very scarcity of wild host fruits that can not be destroyed. It will be found a practicable undertaking to remove such a number of noncitrus host plants at present growing about commercial citrus orchards that the succession of fruits in which the Mediterranean fruit fly can breed during the large portion of the year when citrus fruits are unavailable for attack because of their greenness will be reduced to a minimum, if not entirely done away with. It is under conditions such as can be secured in California and Florida that the excessive mortality occurring in the rind will become a valuable factor in preventing infestation or establishment of the pest, as each fruit will in reality become a trap for stray females. The scarcity of host fruits will also make spraying with poisoned baits a practical undertaking, should it become necessary to resort to artificial methods of control."

A bibliography of 7 titles relating to the subject is appended.

[Serious outbreak of Haltica foliacea] (New Mexico Sta. Rpt. 1914, p. 82).—An outbreak of this flea-beetle upon grapes and young fruit trees is said to have been checked through the use of powdered arsenate of lead applied at the rate of 1½ lbs. to 50 gal. of water. This mixture is said to keep the beetles off the foliage for the most part and to prevent damage if applied in time.

Observations on the life history of Agrilus bilineatus, R. N. Chapman (U. S. Dept. Agr., Jour. Agr. Research. 3 (1915), No. 4, pp. 283-293, pls. 2).—It is stated that at the present time the two-lined chestnut borer (A. bilineatus) is commonly associated with the death of many oaks (Quercus alba, Q. macrocarpa, Q. rubra, and Q. coccinea) in the southern part of Minnesota. In the neighborhood of St. Paul and Minneapolis large numbers of oaks, many of them

on valuable residence property, have been killed during recent years and their death has been commonly attributed to this pest. In some of the outlying districts areas of several acres in extent have been completely devastated, leaving the land treeless.

In this paper the author presents the results of work commenced in the fall of 1913 at the University of Minnesota and continued during 1914 at the Minnesota Station.

Members of the black oak group are said to be slightly more susceptible to attack than those of the white oak group, but in localities where infestation is severe none of the species is exempt. It has often been found that the shoestring fungus (Armillaria mellea) has apparently been the cause of the weakened condition of the trees and that the borers have followed it.

In 1914 adults were first observed on June 17 and increased in numbers until they reached their greatest abundance about July 1. The females were ovipositing from June 19 to July 13, the eggs being deposited in deep cracks between ridges of the bark on the trunks and larger limbs and especially near the ground. Oviposition is said to have lasted from 1 to 5 minutes, from 1 to 10 eggs being laid in a cluster. In the laboratory they hatched in from 10 to 43 days. The newly-hatched larvæ, which measure from 1 to $1\frac{1}{2}$ mm, in length, were found capable of reaching the cambium layer in 24 hours by burrowing for 24 mm. "Observations show that burrows made during the first instar often go obliquely across the grain of the wood or with the grain, the larvæ being indifferent as to whether they go up or down the tree. . . . The burrows measured showed that the larve had burrowed for a distance of 60 to 135 mm, when the first molt took place. . . . The burrows made during the second instar measured about 900 μ in width and took about the same course through the cambium layer, but they were about twice as long. At the beginning of the third instar quite a different course was usually found, especially in green bark on the trunks of trees, where the burrows were almost always transverse to the grain of the wood. The burrows of the fourth instar were about 2 mm, in width and often attained the length of 500 or 600 mm. Where the bark was thick these burrows were quite generally transverse to the grain of the wood. This condition, as well as the oblique course of some of the smaller burrows, is well shown [in a plate accompanying this article].

"At the close of the fourth instar the larva burrows out into the bark, if it is thick enough, and constructs a cell in which it hibernates. Here pupation takes place in the spring. These cells are found in the ridges of the bark on the trunk and larger limbs of the tree and in the wood on small, thin-barked trees and limbs. In constructing the cell the larva burrows out to within a few millimeters of the surface of the bark, withdraws itself 2 or 3 mm., then turns about to one side and excavates around the posterior portion of its body until an oblong cell has been constructed. . . . From the point where the larva entered the bark to the place it emerged from the wood after the first molt the burrow measures 69 mm, in length and 270 μ in width."

While the author has not thus far determined the duration of the instars, larvæ were found in the first stage from July 21 to August 13, and mature larvæ were found in their pupal cells as early as August 7, while the intermediate stage was found throughout this period. It was found that when larvæ were so numerous that they confront each other, one or the other is eaten through as if it were merely cambium tissue. Attention is called to the "wide distribution of the burrows on the tree, from the small branches less than an inch in diameter and between 40 and 50 ft. from the ground down even to the roots, where in one case a larva was found constructing a pupal cell 11 in below the surface of the ground."

The pupal stage which was studied in the laboratory was found to last about 10 days. Observations indicate that in Minnesota the insect normally pupates during the latter part of May and emerges from the cell about the middle of June.

Two parasites were observed, one belonging to the genus Atanycolus, the other an undetermined trichogrammid. As regards control measures it is stated that the culting and burning of infested trees before the emergence of the adults in the spring heretofore recommended is an effective method and needs emphasizing. The need of other methods is thought imperative. The trunks and large limbs were sprayed during the egg-laying season with an iron sulphate and lime-sulphur mixture and others with a Bordeaux mixture as a preventive measure. The results indicate that it was successful in preventing much oviposition.

Contributions toward a monograph of the scolytid beetles.—II, Preliminary classification of the superfamily Scolytoidea, A. D. HOPKINS (U. S. Dept. Agr., Bur. Ent. Bul. 17, pt. 2, tech. ser. (1915), pp. VI+165-232, pls. 8, figs. 17).—This second part of the bulletin previously noted (E. S. R., 21, p. 557) discusses the taxonomy and presents a preliminary classification of the families and subfamilies of the scolytid beetles of the world. The discussion and classification are said to be based upon a study of representatives of about 122 described and undescribed genera and about 1,000 species of North America and other countries in the collections of the U. S. National Museum and certain other museums and institutions of this country.

Following a brief introduction, a discussion of the position of the Scolytoidea and the general anatomy, the taxonomy, including morphological characters, physiological characteristics, geographical distribution in its bearing on taxonomy, etc., is dealt with at considerable length (pp. 169–216). A brief discussion of the species, the genus, nomenclature, types of genera, and a description of a new genus and species (Wcbhia dipterocarpi) from the Philippines follow. The author's preliminary classification of the superfamily is presented in the form of keys to the families and subfamilies, four of the former, Ipidæ, Scolytidæ, Scolytoplatypodidæ, and Platypodidæ, and twenty of the latter being recognized.

A list is presented which shows the position of the principal described genera in the preliminary classification. A bibliography of the literature relating to the subject consisting of four pages is appended.

Descriptions of some weevils reared from cotton in Peru, W. D. Pierce (U. S. Dept. Agr. Rpt. 102 (1915), pp. 16, pls. 2, figs. 6).—This paper presents descriptions of a number of species reared by C. H. T. Townsend from cotton stalks, squares, and bolls in Peru. Two genera and seven species, namely, Mylabris peruanus n. sp., Pachybruchus verticalis n. sp., Spermophagus piuræ n. sp., Eustylomorphus squamipunctatus n. g. and n. sp., Menetypus variegatus n. sp., Sibinia peruana n. sp., Gasterocercodes gossypii n. g. and n. sp. are thus described, and notes on two additional species, namely, Anthonomus vestitus (E. S. R., 25, p. 763) and Geraeus perscitus, are included.

FOODS-HUMAN NUTRITION.

Food industries, H. T. Vulté and Sadie B. Vanderbilt (Easton, Pa.: The Chemical Publishing Co., 1914, pp. VIII+309, figs. 78).—The authors have incorporated in this text-book the material collected as the result of many years' experience in lecturing on the manufacture of foods and food products. The essential steps of the manufacturing processes are described without going to

any great extent into a discussion of the physics and chemistry involved. One chapter is devoted to water supplies and describes briefly the various methods employed for their purification. Other subjects dealt with are the manufacture of cereal products including flour and bread, the manufacture of leavening agents, the sugar industry, the starch industry, animal foods and the packing industry, the production of milk and milk products, the preservation and cauning of foods, and the production of tea, coffee, cocea, spices, and condiments.

Food and diet, JUAN B. PUACOCK (Dept. Agr. New Brunswick Bul. 10, pp. 12).—A popular presentation of fundamental principles of nutrition.

Foods and sanitation, Edith 11. Forster and Mildred Weigley (Chicago; Row, Peterson Co., 1914, pp. 396, figs. 83).—This book is infended for use as a laboratory manual for courses in domestic science. It considers the fundamental principles involved in the economical use of fuel, the processes of sterilization, cooking, and other methods for the preparation of food and food products, and the selection and choice of foods. The subject matter is illustrated by a large number of experiments. The second part of the book is devoted to sanitation in the home and presents briefly data regarding the causes of the more common diseases, together with hints as to how they may be avoided. In this connection chapters are devoted to a discussion of ventilation, heating, lighting, plumbing, water supply, sewage and garbage disposal, and tire protection in the home.

The preservation and care of food, Jean B. Peacock (Dept. Agr. New Brunswick Bul. 9, pp. 12).—A popular presentation of principles of sanitation as applied to the care of food in the home.

Bread cereals and bread, M. P. NEUMANN (Brotyctreide und Brot, Berlin: P. Parey, 1914, pp. VII+615, figs. 181).—This book is intended for use as a text-book in technical and agricultural high schools and in experiment stations, and considers the physical, chemical, and biological properties of the various cereal grains.

A part of the book is devoted to a discussion of the storing of grains with special reference to the organisms which bring about spoiling. Another part deals more in detail with the bread-making cereals, rye and wheat. Both the chemical and biological factors in the preparation of flour and bread making are considered at length. Attention is given to the mechanical side of this question, and the various mechanical processes are described in detail, as well as illustrated by numerous figures and diagrams.

Milling and baking qualities of Victorian wheat, A. E. V. RICHARDSON, P. R. Scott, and F. G. B. Winslow (Jour. Dept. Agr. Victoria, 12 (1914), No. 9, pp. 538-545, figs. 4).—The wheats grown in New South Wales, Victoria, South Australia, and Western Australia, during the season 1913-14 were compared as to physical properties, chemical analysis, and baking qualities.

Rope in bread, Zeckendorf (Nat. Assoc. Master Bakers [Proc.], 16 (1913), pp. 66-78).—This paper summarizes experiments performed for the purpose of testing what constitutes "rope" in bread.

Several species of rope bacteria were isolated which proved very sensitive to acids, but whose spores had great capacity for resisting heat. These bacteria were traced to the flour and not to the yeast. The addition of lactic acid to the dough proved very efficient in preventing the development of rope. Several sanitary recommendations are also made.

The paper is followed by a discussion.

Report on bread wrapping (Nat. Assoc. Master Bakers [Proc.], 16 (1913), pp. 161-193).—This report embodies the results of a chemical and bacteriological study of the question of bread wrapping carried out by commercial chemists

for the National Association of Master Bakers. Analytical data are presented from which the following conclusions in part are drawn;

The wrapping of bread in waxed or paraflin paper is not recommended, as it holds the moisture upon the surface of the bread and produces injurious effects upon the quality of the product. It is stated that the wrapping of bread in porous paper, which allows a gradual loss of moisture and ventilation, may be used with satisfactory results in most cases, except in the cases of Vienna and rye bread, the wrapping of which impairs the crispness and flavor of the crust.

Fenugreek seed, M. Wunschenderf (Jour. Pharm. et Chim., 7. ser., 10 (1914), No. 4, pp. 152-157).—Because of its high nitrogen and phosphorus content this grain should possess great nutritive value. The results of experiments here reported indicate that its disagreeable and intensely penetrating odor and flavor, which prevent its use in medicine, may be removed by germination of the grain and subsequent treatment with boiling alcohol.

All about milk, M. J. Rosenau ([New York]: Metropolitan Life Insurance Co., 1914, pp. 35, figs. 22).—This pamphlet, which is distributed by the Metropolitan Life Insurance Company to its policy holders, points out the dangers from contamination of milk, gives advice regarding the care of milk in the home and the precautions which should be taken in its use, and reviews briefly the relation of milk to infectious diseases.

Viscose—a new casing for sausages, W. P. Conoe, E. C. Fox, and A. J. Acton (Jour. Soc. Chem. Indus., 33 (1914), No. 19, pp. 947, 948).—It is stated that this artificial sausage casing, prepared from wood pulp, consists only of cellulose (hydrate), moisture, glycerin, and a trace of ash. The advantages claimed for this product over the natural casings are that it is cheaper and does not furnish food for the growth of molds and bacteria. It is further claimed that the product is in part at least digestible, and that when eaten it involves the ingestion of a smaller percentage of cellulose than many of the breakfast foods prepared from whole wheat.

Are hardened fats suitable for human food? K. B. LEHMANN (Chem. Ztg., 38 (1914), No. 75, pp. 798, 799).—Hardened products made from peanut, cotton-seed, and sesame oils showed on chemical examination a nickel content of from 0.07 to 6.1 mg. per kilogram. Feeding experiments with dogs led to the conclusion that an ingestion of 2 mg. of nickel per kilogram of body weight is harmless. The author concludes that hydrogenated oils contain inappreciable amounts of nickel and that there is no objection to the use of such fats as foods.

Ice cream studies in Cincinnati, C. Bahlman (Amer. Jour. Pub. Health, 4 (1914), No. 11, pp. 1009-1015).—Laboratory experiments were carried out to determine the effect of the gelatin, eggs, sugar, vanilla powder, and cream used upon the bacterial content of ice cream.

From the results it appeared that the great majority of the bacteria were derived from the cream, comparatively few being contributed to the finished product by the other ingredients. It was also apparent from these investigations that the colon bacillus will generally be present in 10 cc. samples and occasionally in 1 cc. samples owing to the widespread occurrence of this organism.

Proper pasteurization of the cream reduced the bacterial content of the ice cream, and pasteurization of the mixture just before freezing caused a still greater reduction. The taste of the ice cream was not affected by the pasteurization.

The uses of fruit in the household, A. Ethel Dunbrack (Dept. Agr. New Brunswick Bul. 5 (1914), pp. 8).—Recipes and directions for the household canning of fruits are given.

On the analysis and composition of some proprietary foods for infants, J. L. Baker (Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n.

ser., No. 80 (1914), pp. 49-83).—Analytical data are given regarding a number of different kinds of these products.

From these results the foods are classified as follows; Those consisting of dried cows' milk mixed with hydrolyzed starch products or malt flour; foods consisting for the most part of ground meals such as wheat flour, lentils, outmeal, or arrowroot, and in which no alteration of the starch, other than that caused by heating, has taken place during manufacture; foods consisting of ground meals but mixed with a proportion of malt flour or malt extract, (these foods when prepared for use containing the starch in a gelatinized condition); foods in which the starch is altered during the process of preparation according to directions; and partially or wholly altered starch foods, in which the starch or some of it has been converted into soluble products during the process of manufacture. Most of the foods examined showed a deficiency in fat and had a protein content approximately equal to that of average wheat flour.

On the use of proprietary foods for infant feeding, F. J. II. Courts (Rpts. Local Gort. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., u. ser., No. 80 (1914), pp. 3-49).—From this digest of data regarding the nature, chemical composition, and preparation of a large number of proprietary infant foods the general conclusion is drawn that many of such products are not only unfit for the feeding of infants under seven or eight months of age but may cause serious injury. This injury may be caused by the presence of either a greater or less amount of starch or of an excess of carbohydrates in relation to protein and fats or else by a deficiency of fats. A number of recommendations for remedying this condition are made, the most important of which is an argument for proper labeling. The appendixes contain extracts from the laws of other countries regulating the manufacture and sale of proprietary infant foods, and a bibliography.

Increasing the fat content of infants' food, A. Niemann (Jahrb. Kinderheilk., 79 (1914), No. 3, pp. 274–287, figs. 4; abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 16, p. 1291).—The author claims that substitutes for mother's milk contains too little fat and that there is a tendency to increase carbohydrates and decrease fats. Such injury as may result from too high fat content is attributed to the presence of lower fatty acids. It is recommended that this difficulty be overcome by adding to the food butter which has been thoroughly and repeatedly washed with cold water until it has tost all its acid reaction. Enough butter should be added to bring the fat content of the food up to that of normal mother's milk. The food should be warmed and, after the butter is added, shaken thoroughly to form a fine emulsion.

[Food analyses and pure food and drug topics], E. F. LADD and ALMA K. JOHNSON (Noville Dakota Sta. Spec. Bul., 3 (1915), No. 14, pp. 240-248).—In addition to analytical data regarding samples of foods and drugs inspected, general and specific information is given with reference to patent medicines.

[Inspection and analysis of foods and feeding stuffs], B. L. Purcell (Quart. Rpt. Dairy and Food Comv. Va., 1914, June-Scpt., pp. 43).—This report reviews the work carried out under the state food and drug laws, and gives data regarding the inspection of dairies, bakeries, slaughterhouses, hotels, restaurants, and other places where food is packed, prepared, or handled. Analytical data are included regarding a number of samples of a wide range of food products.

Sanitary standard for bakeries adopted by the National Association of Master Bakers (Nat. Assoc. Master Bakers [Proc.], 16 (1913), p. 2).—The text of a sanitary code is given.

Home economics as applied to the choice and preparation of food, Jean B. Peacock (Agr. New Brunswick Dept. Bul. 8, pp. 12),—General information is

given regarding the introduction of labor-saving devices and economy in the selection, choice, and preparation of foods.

The art of good living—French cookery from the 14th to the 20th century, compiled and edited by E. Richardin (L'Art du bien manger—La cuisine française du XIV^c au XX^c siècle. Paris: Editions d'Art et de Litterature, 1914, 5. ed., ed., pp. XL41+946, pts. 27, figs. 113).—Besides over 2.000 recipes, some of them taken from old manuscripts, some collected in remote parts of France, and some contributed by well-known professional cooks and also by distinguished writers, this volume contains reproductions of old paintings representing the preparation and serving of foods at different periods, and an article by the editor in which are summarized data on the food preparations characteristic of different sections of France.

Principles of cooking, EMMA CONLEY (New York: American Book Co., 1914, pp. 206, pl. 1, figs. 41).—This book presents for the student of domestic science fundamental principles of the choice, selection, cooking, and serving of food,

Reducing the cost of living, S. Nearing (Philadelphia; G. W. Jacobs & Co., 1914, pp. 343).—A summary and discussion are given of important factors influencing the cost of living. Chapters are devoted to the economical consideration of the changing form of American living, the increasing demands for service and luxuries, and a number of causes of the advance in prices. A part of the book is devoted to a discussion of remedial measures suggested by the author, among the more important of which are the adoption of simpler methods of living, social education, increased efficiency in food distribution, better conservation of resources, and an increase in the efficiency of labor.

Second Congress of Alimentation, Liége, October 1–4, 1911 (2. Cong. Aliment. Liége, 1911, pt. 2, pp. 499, pts. 2, figs. 9).—A report of the proceedings of the congress is given which includes the transaction of routine business as well as more technical discussions. A number of papers upon various subjects relating to foods and nutrition in addition to those contained in the report of proceedings are included. Among these are the following: What Kinds of Veal Should be Rejected as Human Food, by E. Lonhienne; Food Value of Sugar, by Aulard; Food Value of Sterilized and Preserved Milk, by A. Weymeersch; Artificial Feeding and Digestive Disturbances in Infants, by A. Weymeersch; The Economy and Food Value of Fish, by Koettlitz; and Fermented Milks, by J. Effront.

Biochemical catalyzers in daily life and in the industries, J. Effront (Les Catalyseurs Biochimiques dans la Vie et dans l'Industries. Paris: H. Dunod & E. Pinal, 1914, pp. XI+772).—This volume, which might serve both as a textbook and as a reference work, deals chiefly with the preparation and properties of the enzyms associated with the processes of digestion and metabolism. The industrial application of enzyms is also considered under such topics as the rôle of proteolytic enzyms in the keeping of flour and in bread making, ferments occurring in the manufacture of cheese, etc.

Vitamins, H. W. BYWATERS (Sci. Prog. Twentieth Cent., 9 (1914), No. 34, pp. 225-250, pls. 5, figs. 10).—A summary and digest of data which deals chiefly with the importance of the vitamins in the diet and the relations which they bear to such diseases as beri-beri, pellagra, scurvy, and rickets. The importance of these substances for growth is also considered. Attention is called to the necessity of quality as well as quantity in the diet.

Continuation and extension of work on vegetable proteins, T. B. OSBORNE and L. B. MENDEL (Carnegie Inst. Washington Year Book, 12 (1913), pp. 299-305).—This work has been previously referred to from another source (E. S. R., 32, p. 460).

The effect of air breathed upon the metabolism of protein and carbohydrate food, M. Bache and W. Auel (München, Med. Wehnsehr., 61 (1914), No. 16, pp. 868-870).—The results of a series of animal experiments are here presented and discussed. The following conclusions are drawn:

Breathing air deficient in oxygen produces a nitrogen refention which is probably to be regarded as resulting from the storage of protein. A deficiency of oxygen and an excess of carbon dioxid in the air breathed produce glycosuria in the case of well-nourished animals. An increase of carbon dioxid diminishes phloridzin diabetes and increases the blood sugar content. A lack of oxygen in the air breathed has no effect upon phloridzin glycosuria.

The influence of excessive water ingestion on protein metabolism, J. B. Orm (Biochem, Jour., 8 (1914), No. 5, pp. 530-540).—From the results of a series of experiments in which varying quantities of water were ingested, both during and between meals, the author draws the following conclusions:

"The excessive ingestion of water produces an increased exerction of urinary nitrogen which is most marked on a low protein diet; a retention of nitrogen on the return to normal consumption of water in the case of excessive protein intake; an increase in the percentage of total nitrogen excreted as urea; a marked increase in the excretion of creatin, [and] a decrease in the fecal nitrogen which is interpreted as indicating a more complete utilization of the food protein.

"It is suggested that the results indicate that the influence of the increased water consumption is to accelerate both the catabolic and the anabolic phases of protein metabolism."

Gastro-intestinal studies, III (studies on water drinking, XXI).—Direct demonstration of the stimulatory power of water in the human stomach, O. Bergeim, M. E. Rehfuss, and P. B. Hawk (Jour. Biol. Chem., 19 (1914), No. 3, pp. 345–371, figs. 15).—Men were subjects for experiments in which varied amounts of water were introduced into the stomach by drinking through a Rehfuss tube, and specimens of the stomach contents were then removed at intervals and analyzed for total acidity, free acidity, and peptic activity.

As small a volume as 50 cc. caused in every instance a very distinct stimulation of the gastric glands, as evidenced by increases in both acidity and enzym value.

Since water stimulates the gastric glands to activity when no food is present in the stomach as well as when there is a digestive task to complete, it would seem a waste of "glandular energy" to drink water between meals

The excretion of creatinin by human individuals on a prolonged creatinfree diet, A. I. RINGER and G. W. RAIZISS (Jour. Biol. Chem., 19 (1914), No. 4, pp. 487-492).—Experiments are reported in which individuals received a creatinand creatinin-free diet for a long period of time.

"There was noticeable a gradual and steady decline in the creatinin output per day, a decline that unquestionably lies outside the physiological fluctuations. It is independent of any changes in body weight, and is associated with a steady decline in the creatinin coefficient."

Some observations on the excretion of creatinin by women, MARY HULL (Jour. Amer. Chem. Soc., 36 (1914), No. 10, pp. 2146-2151).—The subjects studied exhibited a low creatinin excretion in comparison with the usual values as found for men.

Metabolism and energy of men, A. Lirschütz (Stoffwechsel und Energiewechsel des Menschen. Leipsie: R. Voigtländer, 1914, pp. XI+189, figs. 17).—This book considers the fundamental principles of human nutrition. Among the subjects included are the chemical nature of foods, the body requirements for

food, the digestive and metabolic processes involved in the maintenance of the body, etc. Descriptions are also given of various types of apparatus which have been used in the study and measurement of energy metabolism and respiratory exchange.

The biochemistry of respiration, H. M. Vernon (Sci. Prog. Twentieth Cent., 9 (1914), No. 34, pp. 251-269).—A summary and digest of data regarding this subject, from which the author draws the general conclusion that the biochemistry of respiration is in the main dependent upon intracellular enzyms. While in some instances this is entirely a hydrolytic process without oxidation, in a majority of organisms the processes are both hydrolytic and oxidative.

Body temperature and pulse rate in man after muscular exercise, E. G. MARTIN, C. M. GRIBER, and T. H. LANMAN (Amer. Jour. Physiol., 35 (1914), No. 2, pp. 211-223, fig. 1).—Experiments with an athlete and an untrained man were conducted for the purpose of ascertaining the relationship between body temperature and the cardio-acceleration of exercise. After muscular exercise, comparisons of axillary temperature and pulse rate were made, leading to the conclusion that no definite parallel exists between persistent cardio-acceleration following exercise and heightened body temperature.

A comparison of the effects upon the blood pressure of physical fatigue produced by prolonged marching with that produced by psychic fatigue resulting from continued mental effort, J. M. LAMY (Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 25. pp. 1913–1916).—Measurements of blood pressure were made upon soldiers making long daily marches, scientists working in the laboratory, and stenographers working industriously for seven hours. A comparison of these figures before and after work showed that in general physical fatigue produced a diminished blood pressure while mental effort increased the blood pressure.

Influence of the environment on the heat production of the human body, Wobsa (Arch. Hyg., 83 (1914), No. 3-4, pp. 123-154).—A mathematical treatise of heat as applied to the maintenance of normal body temperature is given. It is suggested that heat nerves constitute a part of the central heat regulating system.

Energy metabolism under conditions of chronic malnutrition, P. Hárt (Biochem. Ztschr., 66 (1914), No. 1-3. pp. 20-47).—Respiration calorimeter experiments were made with laboratory animals (dogs) which had previously undergone a fasting period. The experimental periods varied in length from 20 to 22 hours and were carried out at a temperature of 27 to 29° C. Measurements were made of the energy production and of the nitrogen and carbon balance.

The metabolism of a dog receiving a daily ration of milk insufficient to meet his energy requirements showed either a slight increase or else a gradual apparent decline. A slight increase in energy metabolism was noted in the case of dogs which showed a relatively small loss of protein in the preceding fasting period as well as during the period of malnutrition. In the case of animals showing a considerable loss of protein a decrease in energy metabolism was observed, but a total milk diet tended to prevent this diminished metabolism.

The specific dynamic action of milk was demonstrated in the case of such animals as had suffered a loss of protein and showed a decrease in energy production. Owing to the marked decrease in the metabolism necessary for maintenance, it is deemed conceivable that the increase of energy metabolism brought about by the ingestion of milk can not make itself evident during the 24-hour heat production period,

ANIMAL PRODUCTION.

An important contribution to statistical theory, R. Pearl (Amer. Nat., 48 (1914), No. 572, pp. 505-507).—The anthor comments on Slutsky's recent contribution extending Pearson's test for the goodness of tit to cover the class of curves formerly not amenable to such test, and the importance of this contribution to biometricians.

The distribution of a Mendelian population in successive generations with continued brother \times sister mating, R. Peara, (Amer. Nat., 48 (1914), No. 565, pp. 58-62).—Starting with a population composed entirely of complete heterozygotes as to a single character, the author follows out the distribution in successive generations with continued brother \times sister mating up to the tenth generation. He shows that the proportion of homozygotes approaches 100 per cent in the same manner as in the case of self-fertilization, but at a slower rate.

Studies on inbreeding.—IV, On a general formula for the constitution of the nth generation of a Mendelian population in which all matings are of brother \times sister, R. Pearl (Amer. Nat., 48 (1914), No. 57.2, pp. 491-494).—The author endeavors to put in the form of a formula the empirical results presented in the above paper.

Inbreeding and relationship coefficients, R. Pran. (Amer. Nat., 48 (1914), No. 573, pp. 513-523, figs. 2).—In this paper the author calls attention to the fact that "an individual may be inbred in 10 generations to within 0.2 per cent as intensely, measured by the coefficients of inbreeding, if his sire and dam are in no way related, as he would be if his sire and dam were brother and sister."

A method is presented for measuring separately what proportion of the observed inbreeding in a particular case is due to kinship of the parents, and what to earlier ancestral relationship. A proposed coefficient of relationship is described and its application illustrated by concrete cases.

Formulas for the results of inbreeding, II. S. Jennings (Amer. Nat., 48 (1914), No. 575, pp. 693-696).—The author expands the work of Pearl (see above) on the results of inbreeding. A general formula is presented for the rate at which organisms become homozygotic through continued brother by sister mating. This consists in "(1) the proportion of individuals that will be homozygotic for any given character after any number of unbroken generations of such inbreeding, (2) the average proportion of the characters of a given individual that will be homozygotic after any number of unbroken generations of such inbreeding. The numerical value so obtained may conveniently be called the coefficient of homozygosis."

The rule is expressed as follows: "The value of the coefficient of homozygosis X for any term (as the nth) is obtained by doubling the numerator and denominator of the fraction expressing the value for the previous term, and adding to the numerator the corresponding (n-1th) term of the Fibonacci series."

Valuation of feeding stuffs by means of chemical analysis, A. SMETHAM (Analyst, 39 (1914), No. 464, pp. 481-491).—Analyses are reported of a number of English feeding stuffs including a number of unusual products from India, Egypt, Brazil, and other places.

The influence of the phosphate and potassic fertilizing of meadows on the chemical composition of the forage, C. Dusserre (Ann. Agr. Suisse, 14 (1913), No. 4, pp. 271–273).—In experiments to determine the influence of phosphatic fertilizing on the composition of grasses, it was found that the phosphorus content was materially increased when phosphorus was added to the meadows in the form of superphosphate.

Studies on the various straws with reference to the crude fiber content and the composition and digestibility under the influences of weathering, F. Honcamp, F. Ries, and H. Müllner (Landw. Vers. Stat., 84 (1914), No. 5-6,

pp. 301–398).—In these experiments with sheep it was demonstrated that the straws of spring grain are not so poor in crude fiber as the corresponding straws of winter grain. The influence of weathering on the percentage content of the various grain straws was proportionately as slight on the organic as on the inorganic constituents, and not so marked as in the protein-rich roughages, such as meadow and clover hays.

It was found that the König method for determining the crude fiber content did not agree in results with the Weender method, also that the König method of determining the pure cellulose and the incrustated material (lignin and cutin) was not accurate. The Cross and Bevan method for determining pure cellulose is recommended as the best.

The digestibilities of summer and winter grown straws were as similar in this respect as in others. Rape and turnip tops as forage material were approximately equal in value, but inferior to the grain straws. The legumes varied to some extent. It is claimed that the value of roughage consists in its starch value and that any classification as to protein and crude fiber content is misleading. The digestible portion of crude fiber is found in the pure cellulose.

Silos and silage, P. V. Ewing (Georgia 8ta. Bul. 110 (1914), pp. 163, 164, 177-190).—This bulletin contains general information on the value of silage as a feed, methods of growing and harvesting silage crops, silage fermentations, the cost of silage, and the feeding of silage to the various classes of farm live stock.

Shock corn for silage, C. II. ECKLES (Missouri Sta. Circ. 71 (1914), pp. 25-28, fig. 1).—It is stated that although not equal to silage from corn put in at the proper stage dry shock corn may be used to advantage in the silo. Tests at the station and elsewhere indicated that approximately 1 lb. of water should be added to every pound of dry fodder. The method recommended for making this silage is described.

The composition, digestibility, and feeding value of molassine meal, cotton-seed meal and hulls, cocoa shells, grain screenings, flax shives, Mellen's Food refuse, and Postum cereal residue (CXX feed), J. B. Lindsey and P. H. Smith (Massachusetts Sta. Bul. 158 (1914), pp. 53-71).—Molassine meal is described as an English product composed of substantially 70 to 75 per cent of cane or beet molasses and from 25 to 30 per cent of sphagnum moss, and has the following approximate composition: Water 18.43, protein 9.32, fat 0.47, nitrogen-free extract 57.51, fiber 6.75, and ash 7.52 per cent.

Six cows were fed by the reversal method, in periods of three weeks' duration, a basal ration of hay, wheat bran, and cotton-seed meal, to which were added definite amounts of either molassine or corn meal. The total average daily nutrients were somewhat less for the molassine ration than for the corn meal ration. The cows produced substantially 14 per cent more milk and 16 per cent more solids and fat on the corn meal ration than they did on the molassine ration. The cost per quart of milk on the corn meal ration was 3.1 cts. per pound, of butter 26 cts.; on the molassine meal ration 3.8 and 33 cts., respectively. Successful trials in feeding this product to horses are also reported. Molasses as a feeding stuff is discussed.

Analyses are given of cotton-seed meal, cotton-seed hulls, cotton-seed hull bran, and cotton-seed feed meal. It was found that low-grade cotton-seed meal contained about 30 per cent less digestible organic matter than the high-grade material. It is stated that the addition of hulls to cotton-seed meal, even in small amounts, lessens its feeding value by decreasing its protein content and impairing its digestibility. Cotton-seed feed meal containing choice cotton-seed meal and cotton-seed hull bran in equal parts has about one-half the feeding value of choice cotton-seed meal. A gradual deterioration in the quality of the

cotton-seed meal sold in Massachusetts, due to the growing tendency to incorporate more hulls, is reported.

Caeao shells are described as the hard, outside coating or bran of the caeao bean. Their use in this country as a feeding stuff has been quite limited, but in Europe they are used as a partial feed for horses and cattle and as an adulterant for oil cakes. Large quantities are also used by the Swiss as a feed for draft oxen. It is held that they act as a stimulant to the nerves and muscles and enable the animals to do a greater amount of work. An analysis is reported as follows: Water 4.5, protein 13.9, fat 4.91, nitrogen-free extract 55.61, fiber 12.65, and ash 8.43 per cent.

In feeding (rials with wheat screenings the fiber did not appear to be at all digestible, indicating somewhat of a depressing effect upon the fiber digestibility of the hay, and the fiber contained in the weed seeds of the screenings was of decidedly inferior character. In chemical composition and digestibility the screenings did not appear to vary greatly from wheat bran.

In experiments with sheep the following coefficients of digestibility were obtained for the several products:

| Kind of feed. | Dry matter. | Protein. | Fat. | Nitrogen- free extract. | Fiber. | Ash. | |
|----------------------|--|---|--|---|-------------------------|---------------------------------------|--|
| Molassine meal | Per ct. 61.98 58.23 57.52 62.94 45.38 | Per et. 41, 74 74, 96 11, 47 71, 79 81, 03 | Per et. 100, 66 100, 18 88 45 92, 68 | Per et, 71, 90 61, 20 73, 46 73, 19 43, 45 | Per ct. 26, 10 50, 66 | Per ct. 79, 48 49, 37 13, 64 | |
| Mellen's Food refuse | 51.15 42.91 | 44.91 19.81 | 83.38 77.90 | 58, 36 62, 18 | 44. 53 13. 39 | | |

Digestion coefficients with sheep for various feeds.

Analyses of these various feeds are included.

Concentrated commercial feeding stuffs, J. D. Turner and H. D. Spears (Kentucky Sta. Bul. 185 (1914), pp. 367-471).—Analyses are reported of alfalfa meal, blood meal, tankage, dried-beet pulp, corn bran, corn chop, cracked corn, corn-feed meal, corn-germ meal, hominy feed, cotton-seed meal and feed, oil meal, rolled oats, rye feed, wheat bran, shorts, middlings, shipstuff, dried brewers' grains, dried distillers' grains, molasses feed, and various mixed and proprietary feeds.

Concentrated feeding stuffs and registrations for 1914, C. S. CATHCART (New Jersey Stas. Bul. 271 (1914), pp. 3-85).—Analyses are reported of the following feeding stuffs: Alfalfa meal, brewer's dried grains, buckwheat bran, buckwheat middlings, buckwheat offal, corn-feed meal, corn-and-cob meal, corngerm meal, cotton-seed meal, cotton-seed meal and hulls, distillers' dried grains—corn and rye—dried-beet pulp, feeding flour, gluten meal, gluten feed, hominy feed, hominy meal, linseed meal, malt sprouts, meat meal and beef scrap, mustard bran, oat hulls, rye bran, rye middlings, shredded wheat, wheat bran, and wheat middlings, and various mixed and proprietary feeds. A discussion of the findings under the new law and other data are included.

Experiments on the nitrogen economy value of sodium acetate for ruminants, E. Pescheck (Biochem. Ztschr., 62 (1914), No. 3-4, pp. 186-218).— Experiments of Weiske and Flechsig in 1889 are discussed in which sheep were fed hay, peanut cake, potato starch, and sugar as a basal feed with approximately 80 gm. per day of sodium acetate, the addition of sodium acetate reducing the nitrogen output in the urine over that in animals fed on the basal ration alone. Later experiments by Gabriel in which salt was added to the

basal ration confirmed these results, the nitrogen output in the urine and feces being greater on the basal ration alone than when from 10 to 30 gm, of NaCl was fed with the ration.

The principles and practice of judging live-stock, C. W. GAY (New York: The Macmillan Co., 1914, pp. XVIII+413, figs. 159).—This book, which is one of the Rural Text-book Series, gives practical instruction in methods of judging live stock.

Stock breeding in Belgium, J. L. Frateur (Vic Agr. et Rurale, 3 (1914), No. 24, pp. 666-672, figs. 2).—This includes data on the importation and exportation of horses, cattle, sheep, and other classes of farm stock in Belgium, and an account of the status of live stock breeding in that country.

The cattle of Demonte, E. MASCHERONI (Indus. Latt. c Zootce., 12 (1914), No. 19, pp. 292-295, figs. 5).—An account of the origin, breed characteristics, and utility value of the breed of cattle indigenous to Demonte, Italy.

Cattle feeding on the plantation and farm, W. II. DALRYMPLE (Louisiana Stas. Bul. 151 (1915), pp. 3-13, fig. 1).—This bulletin is a general discussion of the opportunities for successful cattle feeding in Louisiana, especially on the sugar plantation where molasses and cane-top silage may be used to advantage. The experience of one feeder is cited in which 49 lbs. of corn silage, 6 lbs. of blackstrap molasses, and 5 lbs. of cotton-seed meat per head per day were fed 111 days, a net profit of \$6.52 per head being realized.

Digestion and metabolism of a steer when placed on a continuous ration of corn silage, P. V. Ewing and C. A. Wells (Georgia Sta. Bul. 109 (1914), pp. 145–158, figs. 3).—In a digestion experiment with a 14-month-old Shorthorn steer in which eight 10-day trials, with periods of about seven days intervening, were made, and in which he was fed all the silage he would eat twice daily, this being regarded as about a maintenance ration, average digestion coefficients were obtained of 61.3 per cent for dry matter, 27 for nitrogen, 51 for fat, 62.4 for nitrogen-free extract, 69 for fiber, and 42.2 for ash. It was demonstrated that "when an animal is placed on a low plane of nutrition it does not more completely digest the feed given it as time goes on. The tendency seems to be slightly in the opposite direction. Not only is digestion quite uniform in its intensity in different individuals of the same species, but with the same animal it remains fairly constant when taken over a rather long period of time.

"The digestibility of the feed is somewhat retarded in an animal after having been on a low plane of nutrition for a time, which is probably the result of a general retardation of the digestive functions. The maintenance ration of a steer does not decrease as time goes on through the steer's ability to take more of the nutrients from the feed given him, but by virtue of his physiological behavior the steer puts the digested nutrients supplied him to a more economical use.

"Silage alone is an unsatisfactory feed because of its deficiency in nitrogen, and a steer placed on this ration is forced to draw on his stored nitrogen to meet the demands of the body for nitrogen. While the animal was eating all the silage its appetite would permit, there was every indication that it could have digested more silage if it could have consumed it. The appetite seems to act in some way as a check on the efficiency of the animal.

"Water consumption seems to be very greatly influenced by the moisture content of the feedstuff, and it is possible for the water of a succulent feed, such as silage, to supply all the water required by a steer for at least a number of days. The disposition of an animal is materially affected by being placed on a low plane of nutrition, as indicated by restlessness, nervousness, inclination toward viciousness, a very abnormal appetite, constant grinding of the

teeth, and a drawn or humped attitude when standing. After having been starved or stunted for a period this animal was apparently able to overcome the effects, which suggests that an animal has the capacity to increase its rate of gain for a short period of time, at least, in order to compensate for a low rate at some previous period."

[Feeding preserved milk to calves], G. A. Brown (Michigan Sta. Rpt. 1914, pp. 206-210).—In trials to determine the advisability of using formaldehyde as a preservative for skim milk fed to 4 to 7-week-old calves for 21 weeks, 7½ cc. of 40 per cent formaldehyde being used to each 100 lbs, of milk, it was found that in general the calves suffered no deleterious effects from the preservative, and as compared with calves fed sweet milk or sour milk, made slightly greater gains at somewhat lower cost. From records kept of the after development of these calves it was found that those which had been fed the preserved milk continued to make the cheapest gains, followed by the sweet milk fed calves and the sour milk fed calves.

For the entire experiment the calves fed sweet milk made a total gain of 1,997 lbs., costing 5.41 cts. per pound; those fed sour milk 2,189.4 lbs., costing 5.43 cts. per pound; and those fed the preserved milk 2,537 lbs., costing 5.23 cts. per pound.

It is concluded, however, that the work should be carried on with a large number of calves before definite conclusions can be drawn.

The characteristics of the hybrid zebu, C. Pecci (Agr. Colon. [Italy], 8 (1914), No. 10, pp. 613-619), pls. 3).—Experiments are reported in crossing the zebu on various Italian and European breeds of cattle. The hybrid showed greater resistance to disease, earlier maturing qualities, and more marked beef qualities.

Rations for breeding ewes, H. Hackedorn (Missouri Sta. But. 120 (1914), pp. 31-57. figs. 9).—Lots of 2 to 4-year-old Colorad) ewes, weighing approximately 86 lbs., were fed during the winter season with the results shown in the following table:

| Summary | of | erre-fecc | lina | crne | riments. |

The results are summarized as follows:

"Clover hay and grain proved more efficient as a ration for breeding ewes than timothy hay and grain. Clover hay alone was sufficient to maintain pregnant breeding ewes up to lambing time. After lambing, the addition of grain to the ration proved advisable.

"Corn silage when fed with clover hay, with grain, and with both clover hay and grain, proved a slightly better roughage than corn stover fed with the same combination of grain and clover hay. Moldy or extremely sour corn silage is a dangerous feed for sheep. Eleven ewes were lost in this experiment in one week from accidentally feeding moldy silage. A ration of corn silage, clover hay, and grain proved to be the most efficient means of utilizing silage.

"A ration of grain and corn stover gave very satisfactory results when sufficient and proper kinds of concentrates were used. Corn stover, clover hay, and grain proved to be the most satisfactory method of utilizing stover. Corn silage and stover both proved to be better roughages than timothy hay when fed with grain."

 Λ table is given showing the capacity for sheep feeding of silos ranging in capacity from 45 to 314 tons.

A survey of sheep and lamb production in 1914, R. M. MURPHY (Tennessee Sta. Bul. 110 (1914), pp. 248-264, figs. 2).—This bulletin is a general discussion of the sheep industry in Tennessee and includes sections on the extent of the industry, causes of increase and subsequent decline, kinds of sheep and sources of supply, system of management, marketing the crop, clipping and marketing wool, lamb and wool clubs, dogs, needs of the sheep industry, and a suggested dog law.

Silage for horses and mules, E. A. Trowberdee (Missouri Sta. Circ. 72 (1914), pp. 29-32, fig. 1).—Ten yearling mules, weighing approximately 650 lbs. each, were fed for 90 days an average daily ration of 6.5 lbs. of ear corn, 8.6 lbs. of mixed hay, and 4 lbs. of corn silage. The mules made a gain of only 4.8 lbs. during the period. No ill results were seen from the use of the silage but the mules did not consume large quantities of it. This it is thought may have been due to the fact that the silage was made from rather immature corn.

Successful experiments in feeding silage to horses and mules, conducted at the North Carolina and Pennsylvania stations (E. S. R., 15, p. 901; 28, p. 172; 29, p. 773) are cited. It is advised that corn silage should always be fed in combination with other feeds, and that under no circumstances should spoiled silage, either moldy or rotten, be fed to horses and mules.

Studies on the physiology of reproduction in the domestic fowl.—VIII, On some physiological effects of ligation, section, or removal of the oviduct, R. Pearl and Maynie R. Curtis (*Jour. Expt. Zool., 17* (1914), No. 3, pp. 395–424).—The authors summarize the results of their studies as follows:

"Neither the ligation, section, nor entire removal of the oviduct causes the degeneration or prevents the further growth of the ovary. The pressure of the inclosing funnel is evidently not necessary to ovulation since yolks are ovulated into the body cavity after the ostium is sewed or ligated or after the entire duct is removed. Internal pressure due to continued yolk formation is probably the most important factor in the normal rupture of the follicle, since closing the funnel or removing the duct apparently does not greatly delay ovulation. There are cases of unoperated birds with normally functioning ovaries, and oviducts apparently capable of functioning which do not produce eggs because of some anatomical or physiological condition of the mouth of the oviduct which prevents the entrance of the yolk.

"The fate of yolks or eggs set free in the body cavity depends apparently upon the physiological vigor of the bird. First, they may cause serious metabolic disturbances which result in the death of the bird; second, they may be absorbed rapidly from the general peritoneal surface; or third, they may be walled off by the peritoneum and then absorbed. The material from the resorbed yolks or eggs is apparently utilized in body metabolism since all such birds which were in good health at the time of autopsy were very fat. The removal of the greater portion of an oviduct does not cause the atrophy of any remaining portion. The whole or any remaining part of an oviduct sewed at the funnel, ligated at any level, or with parts removed, passes through growth and cyclic changes coordinated with changes in the ovary exactly as an unoperated duct.

"The stimulation of the advancing egg is necessary for the discharge of the secretion of the duct, since a duct closed at any level functions only to the point where the passage is interrupted. When any portion of the ventral ligament is removed it is not replaced but all remaining portions develop. The forward portion of the ventral ligament is necessary for the reception of the yolk by the funnel. The muscle bundles which arise from the nunscular cord in the ventral ligament along the uterus are probably an important part of the normal apparatus which expels the egg."

Studies on the physiology of reproduction in the domestic fowl.—IX, On the effect of corpus luteum substance upon ovulation in the fowl, R. Pearl and F. M. Surface (Jour. Biol. Chem., 19 (1914), No. 2, pp. 263-278).—In these studies it was shown that "the desiccated fat-free substance of the corpus luteum of the cow, when injected in suspension, in proper dosage, into an actively laying fowl immediately inhibits ovulation. The duration of this effect varies with different birds from a few days up to two to three weeks. After the bird begins ovulating again the laying goes on unimpaired. The same effect is produced by the injection of extracts of the lutear substance, either intravenously or intra-abdominally. The active substance in producing the inhibition is inactivated by boiling." It is stated that these results are of interest zoologically as well as physiologically. It suggests the possibility of finding a chemical substance which will stimulate or activate the ovulation mechanism. Also, "the fact that the same chemical substance inhibits ovulation in mammals and birds, which latter do not possess any organ corresponding to the one which produces the substance in mammals (the corpus luteum) suggests that natural selection probably had nothing to do with the evolution of either the organ or the function in the mammals."

Studies on inheritance in poultry.—II. The factor for black pigmentation in the White Leghorn breed, P. B. Hadley (*Rhode Island Sta. Bul. 161 (1914*), pp. 449-460, pl. 1).—This is a continuation of work previously noted (E. S. R., 30, p. 71).

The author demonstrates that the White Leghorn carries in itself all the factors necessary for the production of black pigmentation in the F_2 and later generations of crosses with any nonblack race. In these experiments the stock used was pure White Leghorn and White Plymouth Rock, line-bred for many generations. The crosses were made in only one direction, White Leghorn male \times White Plymouth Rock females. The majority of the birds were raised to five months of age, and some were kept until they were mature. On the basis of the hypothesis that the White Leghorn does not earry the factor, or factors, for black pigmentation, but contributes only one of two necessary factors, while the White Plymouth Rock contributes the other, there was a wide departure in the actual results from the expected results; while on the

basis of the hypothesis that the White Leghorn carries in itself all the factors for black pigmentation, the actual and expected results corresponded very closely.

The results of this study indicate that the admixture of Leghorn blood can not be made without introducing complexities in either pattern or color,

Seaweed for packing birds, M. Dikobra (Nature [Paris], 42 (1914), No. 2134, pp. 339-340, figs. 5; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases, 5 (1914), No. 7, p. 918).—A new method of packing birds is described, which consists "in placing the body in a natural bag formed by the lamina of a certain seaweed occurring in islands off New Zealand. Birds can be kept in good condition for several years in this way."

DAIRY FARMING-DAIRYING.

Report of the dairy husbandry department, O. F. HUNZIKER (Indiana Sta, Rpt. 1914, pp. 37-47).—In continuing work previously noted (E. S. R., 30, p. 575) three lots of five cows each were fed for six months corn silage and alfalfa as roughage and a grain rating as follows; Lot 1, corn meal, wheat bran, and cotton-seed meal 4:2:1 by weight; lot 2, ground corn and wheat bran 1:1; lot 3, ground corn and oats 1:1. The gains in weight per head were, respectively, 19.64, 19.8, and —7.56 lbs., the milk yields approximately 1,435, 1,409.7, and 1,430 lbs., the milk fat yield 57.6, 56.72, and 56.86 lbs., the total dry matter consumed per pound of milk 0.97, 0.99, and 0.94 lb., and the average daily cost of feed 21.1, 20.7, and 20.5 cts, per head. The cost per pound of fat was 22.1, 22.2, and 22.5 cts., respectively.

It is concluded that the use of wheat bran or ground oats in a dairy ration is to be recommended, although the selection should depend largely upon its availability.

In an experiment in which three lots of six or seven calves were fed for 42 weeks as follows: Lot 1, an average of 11.2 lbs, skim milk per head per day; lot 2, 1.41 lbs, per day of home-mixed calf meal consisting of hominy meal, linseed meal, red dog flour, and dried blood equal parts by weight; and lot 3, 1.06 lbs, per day of a commercial calf feed, all of the lots receiving whole milk until gradually displaced by the other feeds, and also receiving a dry mash and a roughage feed of alfalfa hay and silage, the average daily gains per head were 1.26, 1.04, and 0.78 lbs., the average daily cost of the ration 7.1, 7.4, and 9.67 cts., and the cost per pound of gain 5.6, 7.2, and 13.6 cts., respectively. This experiment is being continued.

In order to determine the accuracy of the different methods of sampling milk, including daily samples, composite samples with aliquot portions or equal portions, samples every second day, every third day, every fourth day, and every fifth day, tests were made of 4,900 of samples taken by these methods. The averages of the percentages of fat and pounds of fat of all samples and for the entire 14 days show "a remarkable uniformity of results secured by the several methods."

Report of an experiment on the feeding of dairy cows, T. MILBURN and R. RICHARDSON (County Council Lancaster, Ed. Com., Agr. Dept., Farmers' Bul. 28 (1915), pp. 13).—An analysis of palm-nut cake is given as moisture 12.29, protein 18.79, fat 6.87, carbohydrates 48.84, fiber 9.51, and ash 3.7 per cent.

Two lots of six cows each were fed by the reversal method for two months a basal ration of roots, meals, and hay, lot 1 receiving daily in addition from $4\frac{1}{2}$ to 5 lbs. of decorticated cotton cake, and lot 2 from $6\frac{3}{4}$ to $7\frac{1}{2}$ lbs. of palm-nut cake. The cotton-cake fed lot yielded a total of 8.852 lbs. of milk during the

experimental period, while the palm-nut cake fed lot yielded 8,743,25 lbs. In every case where there was a change to palm-nut cake a drop in yield occurred, whereas in cases of changes to cotton cake there were two increases and two decreases. The change in feed did not materially affect the composition of the milk, and the palm-nut cake, though fed in fairly large quantities, had no undesirable effects on the butter produced.

It is stated that palm-nut cake is a perfectly safe feed for milch cows, and might give better results if fed as a part of the cake portion of the ration (2 to 3 lbs.) than were obtained in this experiment where one cake only was introduced.

Murne Cowan, new world's champion [cow], R. G. Murphy (Hoard's Dairyman, 49 (1915), No. 7, p. 247, figs. 3).—An account of the 10-year-old Guernsey cow, Murne Cowan, which has recently completed her year's record of 24,008 lbs. of milk containing 1.098.18 lbs. of fat. Her largest milk yield in 24 hours was 82.3 lbs. In seven days she produced 565.8 lbs. of milk containing 24.41 lbs. of fat and in one mouth she produced 2.361.5 lbs. of milk and 102.02 lbs. of fat. It is said that Murne Cowan weighs 1.320 lbs., 100 lbs. more than when the test was begun, and that to all appearances the making of this record has not injured her in the least.

Experiments with the Sharples mechanical milker, J. J. Hooper and J. W. NUTTER (Kentucky Sta. Bul. 186 (1914), pp. 475-510, figs. 12).—In tests with milking machines at the Kentucky Station it was demonstrated that there was no appreciable or permanent decrease in the milk production during a 30-day period when the cows were becoming accustomed to the mechanical milker,

At the Elmendorf farm, Lexington, Ky., it was found that 25 cows milked with the machine decreased 10.5 per cent in their milk yield in May as compared with their production in February, while 25 other cows during the same period milked by hand decreased 18.5 per cent. The machine-milked cows produced less milk during March than during April. After the machine at the station had been in use for seven mouths, it was discontinued for two weeks and the cows during that period were milked by hand. The cows did not as a rule respond with a larger milk yield when hand milked. The cows were stripped by hand after being machine-milked, the average strippings amounting to less than one pint.

The average percentage of decrease in milk yield for each period of 30 days was found to vary from 3.4 per cent in the second month to 21.5 per cent in the twelfth month. This decrease is somewhat larger and was not so uniform as was found in 323 animals at the Wisconsin Station (E. S. R., 28, p. 272).

An average of 71 milkings showed that the time consumed by a unit in milking a cow was 3.99 minutes, the time to strip 0.83 minute, the weight of strippings 0.92 lb., and the milk produced with strippings added 11.67 lbs.

It was found that two men operating four units can milk 28 cows, strip and feed them, and carry the milk to the dairy room in 43.4 minutes. With hand milking this same operation performed by two men required 1 hour and 20 minutes. The total time consumed in washing the parts of the machine each day was 75 minutes.

Salt brine and sal soda solutions were found unsatisfactory in cleaning the parts of the milking machine. A solution consisting of unslaked lime and water 1:9 is now used and found to kill practically all bacteria.

Bacteriological tests made of the various solutions showed that whereas those using brine and sal soda contained a large number of bacteria, limewater contained from 0 to 130 bacteria per cubic centimeter. Bacteriological tests made of milk produced with the machine showed an average of 3.657.6 bacteria

per cubic centimeter, and where the strippings were added, an average of 12,221.5 bacteria per cubic centimeter. Tests on average milk from the station dairy showed 10,620 bacteria.

A comparison of hand and machine milk showed a somewhat lower bacterial content in the latter. In comparing the tests of milk drawn with the machine from many different cows it appeared that some cows produced milk that contained a large number of bacteria, but ordinarily the milk was almost free from bacteria as it came from a healthy udder. It was found advisable to draw a stream of milk from each teat before the cups are applied as this milk contains a large number of bacteria. A high bacterial count followed lapses in scrupulous cleanliness in handling the machine and its parts.

Development and present situation of milk recording and bookkeeping associations in Denmark, A. C. Duborg (Abs. in Internat. Inst. Agr. [Rome], Mo. But. Agr. Intel. and Plant Diseases, 5 (1914), No. 9, pp. 1234-1236).—An account of the work of the milk-recording associations in Denmark.

[Prices paid to farmers for milk] (Cream, and Milk Plant Mo., 3 (1915), No. 6, pp. 23, 24, fig. 1).—From statistics compiled by the Dairy Division and the Bureau of Crop Estimates of this Department it is estimated that the average price paid to farmers for milk in 1913 was 3,849 cts, per quart, and in 1912, 3,565 cts. The price decreased from 4,2 cts, in January to 3,3 cts, in June and then gradually increasing to 4,3 cts, in December. It appears that milk was at its highest in New England, the average price for the year being 4,571 cts. It was lowest in the east North-Central States, the year's average being 3,503 cts. The greatest range in prices was found in the Middle Atlantic States, where the December price was 4,187 cts, and the June price 2,912 cts.

Studies on milk, R. Windisch (Kisérlet, Közlem., 17 (1914), No. 2, pp. 221–223).—In these studies a variation in the dry matter in the milk of morning and evening milkings from 0 to 0.1 per cent was noted in 75.47 per cent of the cases, from 0.1 to 0.2 in 21.69 per cent, and greater than 0.2 per cent in 2.81 per cent of the cases. The Ackermann refraction was found to be a fairly accurate method of distinguishing the milk from cows of fresh lactation from those well along in the lactation period.

Bacillus abortus in market milk, Alice C. Evans (Jour. Wash. Acad. Sci., 5 (1915), No. 4, pp. 122-125).—A method by which B. abortus may be isolated and identified is described as follows:

"The milk is plated on ordinary lactose agar, to which there is added just before pouring into the plate, at a temperature of about 50° C. 10 per cent of sterile blood serum. After incubating for four days at 37°, a certain area of the plate, large enough to include several colonies of B. abortus, should they be present, is selected, and the colonies are transferred to a nutrient broth containing 1 per cent of glycerin. Colonies from a similar area are transferred to tubes of whole milk containing litmus.

"The growth in the glycerin broth is quite characteristic. There is a medium amount of growth in tiny, compact, spherical masses which settles to the bottom of the tube and does not cloud the broth. In litmus whole milk there is an abundant growth in the cream layer, with a gradual development of acid. Cultures in litmus milk from which the cream has been removed grow sparingly, with no apparent effect. On plain infusion agar slopes the growth is in very small, separate colonies, which are scattered over the whole surface of the slope, if it happens to be moist at the time of inoculation; or the colonies are confined to a ribbon-like growth along the line of inoculation, if the agar is comparatively dry when inoculated."

The incidence of tuberculosis in childhood.—The prevalence of tubercle bacilli in the Edinburgh milk supply, A. P. MITCHELL (Jour. State Med., 23

(1915), No. 2, pp. 44-54).—Samples of milk collected from Edinburgh milk shops show a high incidence of tubercle bacilli, which fact is thought to account for the prevalence of bovine tubercular infection of children in that city. More stringent inspection and regulation of dairy farms is urged.

The viability of the typhoid bacillus in sour cream, C. KRUMWIEDE and W. C. Noble (Amer. Jour. Pub. Health, 4 (1914), No. 11, pp. 1006-1008).—This investigation tends to show that the acids produced in sour cream gradually kill the typhoid bacillus, at a rate proportional to the degree of acidity and the number of organisms present.

"With a moderate contamination, the typhoid bacilli are killed in about four days. With a heavy contamination or where initial multiplication has taken place, a longer time may be required. For this reason a clean cream which soured slowly would be more dangerous if contaminated, as an initial multiplication of the typhoid bacilli would occur and a longer time would be required to destroy the bacilli."

An investigation into the keeping properties of condensed milks at the temperature of tropical climates, W. W. O. BEVERIDGE (Jour. Roy. Army Med. Corps, 22 (1914), No. 1, pp. 1–8).—The author concludes from his observations that "the change in color of certain kinds of condensed milks in tropical climates is presumably due to brown color being developed by reducing sugars in solution at a certain temperature, and is likely to be more marked with an increase of acidity due to bacterial fermentation; the presence of iron in the ferric state also plays a part in the production. In sterile condensed milks, chiefly found among those brands which contain no added sugar, changes are not noticeable. Sterile uncondensed tinned milk also shows no change even after incubation at 37° C. (98.6° F.) for many months.

"The increase of acidity is brought about by bacterial activity resulting from the increased temperature, and hydrolysis of the sugar follows. The bacteria concerned in the change are spore-bearing bacilli which produce an acid fermentation of the proteins. In milks containing only Gram-positive staphylococci a brown color is probably never produced. It would seem that the depth of the brown color is dependent on the amount of reducing sugar produced or of iron present, and is likely to be more intense in sweetened milks, owing to the reduction of the added cane sugar.

"The increase in consistency, noticed in connection with the brown coloration in sweetened milks, is also due to bacillary fermentation, and some of the protein is consequently rendered insoluble."

[Butter analyses], J. C. Brünnich (Ann. Rpt. Dept. Agr. and Stock [Queensland], 1913-14, pp. 65, 66).—Analyses of a large number of butter samples gave an average moisture content of 14.97 per cent for salted butter and 15.69 per cent for unsalted. There was 0.44 per cent of boric acid in the salted butter and 0.27 per cent in the unsalted.

Moldiness in butter, C. Thom and R. H. Shaw (U. S. Dept. Agr., Jour. Agr., Research, 3 (1915), No. 4, pp. 301-310, fig. 1).—From mycological and chemical examinations made of characteristic samples representing the range of conditions and appearances found in commercial butter obtained through the inspection service of this Department, the authors conclude that "mold in butter usually takes three forms, viz. (a) orange-yellow areas with a submerged growth of mycelium are produced by Oidium lactis; (b) smudged or dirty green areas either entirely submerged or with some surface growth are produced by species of Alternaria and Cladosporium; (c) green surface colonies are produced by species of Penicillium, or, more rarely. Aspergillis, either upon the butter, causing decomposition, or upon the container or wrappings, injuring the appearance of the sample in the market,

"Species of Oïdium, Alternaria, and Cladosporium can not develop in butter containing 2.5 per cent of salt. The occurrence of any of these forms in a sample of butter indicates low saiting. Excess of curd favors mold growth. Well-washed butter is less subject to mold. Leaky butter, i. e., butter from which water of buttermilk exudes and collects in the wrappings or in the container, furnishes the best conditions for the beginning of mold growth. From these wet areas colonies may spread to the butter itself.

"Wet surfaces, wet wrappings, or high humidity, are essential to mold growth in butter. Mold will not grow upon the surface of a piece of butter exposed to humidities of 70 per cent or lower. The water in the butter is thus not sufficiently available to the mold to support the development of a colony, unless evaporation is reduced by high humidities. In closed packages, wet or damp cellars, or carefessly packed masses with cracks or fissures in which moisture collects, mold may seriously injure the appearance of butter packages or actually induce great changes in the butter itself. Salt up to 2.5 to 3 per cent in butter is sufficient to eliminate mold or reduce it to negligible amount. This is equivalent to the use of a 12 to 15 per cent brine."

A bibliography of ten references is given.

VETERINARY MEDICINE.

A system of veterinary medicine, edited by E. W. Hoare (Chicago; Alexander Eger, 1915, vol. 2, pp. XVIII+1623).—This second volume of the work previously noted (E. S. R., 29, p. 476) deals with general diseases and includes a section on parasites and parasitic diseases. An index to the two volumes is given.

Report of the veterinary department, R. A. Craic (Indiana Sta. Rpt. 1914, pp. 72-76).—During the year 38 per cent more of antihog-cholera serum was prepared than in any previous year. In the field work all healthy hogs were vaccinated by the serum-simultaneous method and the cholera hogs were given the serum alone. Many deaths resulted amongst the vaccinated healthy hogs due to infection of the vaccination wound at the time of vaccination or shortly afterward.

A few of the simultaneously vaccinated herds lost their immunity in from six weeks to six months post vaccination. In nearly every case the pigs that lost the immunity received only 0.5 cc. of hog cholera blood. "Field experience indicates that it is not advisable to administer less than one cc. of virus, or simultaneously vaccinate pigs that weigh less than 50 lbs., especially if the mother is actively immune."

In the hog cholera investigations hog cholera blood and virulent normal salt solution were studied with the ultramicroscope and various culture media such as milk, hay, and meat infusions, bouillon, and sugars were used in combination with filtrates of virulent blood. More than 60 germ-free filtrates were studied.

For the purpose of determining variations in the virulence of hog cholera blood at different periods in the disease, virus was secured by tail bleeding a cholera hog four and six days after it had been inoculated. Twelve pigs given the four-day virus lived an average of 24 days while those given the six-day virus lived only 21 days.

A mixture consisting of one part hog cholera blood and two parts normal salt solution was incubated at a temperature of 37.5° C. for 24 hours. The different lots of virus were then heated from one to two hours in a water bath at temperatures ranging from 60 to 65°. Of 62 pigs inoculated with

the heated virus, 60 of the pigs died of acute hog cholera, while of 23 pen exposure checks, 21 died of hog cholera.

Inoculation by the intravenous method was found to yield a less potent antiserum than that given when the inoculation of virus is made intramuscularly. Ten hog cholera cures (nine proprietary and sodium cacodylate) were tried, but no preventive or curative properties were found.

"Samples of the different antihog-cholera sera sold by the commercial tirms have been bought and tested for both potency and purity. The bacterial counts of the different makes of serum have varied from 30,000 to 125,600,000 bacteria to the cubic centimeter. Forty tests for potency have been made. Thirteen of these tests proved unsatisfactory, one or all of the pigs in the different tests that were vaccinated by the simultaneous method dying of hog cholera." From a large number of post-mortem examinations of birds from different poultry farms in the State and the reported losses, it is concluded that mixed septicemia causes more loss to poultrymen than any other one disease. An attempt to control this infection on one poultry farm by the use of a bacterin failed.

Report of the bacteriologist, W. GILTNER (Michigan 8ta, Rpt. 1914, pp. 210-225).—In a study of the milk of animals infected with contagious abortion organisms having a close resemblance to the Bacillus abortus were isolated from the stomach of an aborted calf and from the milk of a cow after abortion.

As to the comparative virulence of avian, human, and bovine types of B. tuberculosis, the results of a rabbit experiment "would lead one to believe a close relationship exists between the avian and bovine types as regards the degree of virulence. Furthermore, if the type of disease produced in rabbits is indicative of the type that might be produced by the application of the same methods in calves, the use of living cultures of avian tubercle bacteria in bovine vaccination is unsafe and unwarranted."

In studying contagious epithelioma or "sore head" in chickens, a vaccine was prepared "from the diphtheritic membrane which developed in the mouth of the diseased birds. This material was ground in a sterile mortar, suspended in salt solution, and heated at 60° C. for two hours. Injections of 1 cc. were made into the muscles of the leg in some cases and the breast in others. Twelve birds were treated and one not treated was placed in a pen with those treated. This untreated bird died later and an autopsy showed a diphtheritic condition of mouth, larynx, and pharynx. Those birds which were sick when treated all recovered with but one exception. One of the sick treated birds was kept in the pen and later the disease redeveloped, about two months after apparent recovery. This would indicate an immunity of short duration."

In work on contagious abortion, an additional experiment was made to study the effects of dead and living cultures of the abortus bacterium upon the morphological blood elements "and blood reactions, both in open females and during pregnancy, a study of the pathologic anatomical changes as a result of these culture injections." It was found from a comparative study of the agglutination and complement fixation test that little can be determined from these tests about the probability of an individual aborting, nor can anything be predicted as to the probability of the reacting animal becoming a source of danger to susceptible animals. "The complement fixation test will pick out more reactors than will the agglutination test but on the other hand animals may react to the agglutination test and not to the complement fixation test. . . . The use of living cultures of the abortus bacillus on open females and dead cultures on pregnant females has been applied to a few herds with the object of observing their immunizing effects. The results of this work can not be fully appreciated as

yet but they are not encouraging, on the other hand they lead to the belief that these injections may result injuriously in some cases and beneficial in others."

Annual report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, for the year 1913-14, A. SMITH and P. J. KERR (Ann. Rpt. Bengal Vet. Col. and Civ. Vet. Dept., 1913-14, pp. 6+111+9+VIII+3).—This is the usual annual report (E. S. R., 30, p. 778).

E. Merck's annual report of recent advances in pharmaceutical chemistry and therapeutics (Merck's Ann. Rpts., 27 (1913), pp. 589).—This is a review of the literature pertaining to these topics for the year 1913. Special articles on nuclein and nucleic acid and preparations used for radiographic examinations are included. A bibliographic index is appended.

Bacterial antiferments.—Studies on ferment action, XVII, J. W. Jobling and W. Petursen (Jour. Expl. Med., 20 (1914), No. 5, pp. 452-467, figs. 2).—This work was done with several kinds of bacteria, including the tubercle bacillus. Intact bacteria are said to resist digestion by trypsin because no protein substratum is exposed. Dried organisms resist digestion in a degree proportional to their content of ansaturated lipoids. Lipoidal extractives were found to reduce the resistance to tryptic digestion.

"The extracted lipoids (saponified) are antitryptic in a degree proportional to their unsaturation. The inactivation of the antiferment in Gram-negative organisms is probably due to changes in the degree of lipoidal dispersion. Bacteria adsorb lipoids from the serum when incubated at 37° C. Such organisms when dried are found to be more resistant to tryptic digestion than untreated organisms."

Lipoids as inhibitors of anaphylactic shock.—Studies on ferment action, XVIII, J. W. Jobling and W. Petersen (Jour. Expt. Med., 20 (1914), No. 5, pp. 468-476, fig. 1).—"The antitryptic titer of the serum can be increased by subcutaneous injections of serum lipoids (antitrypsin) and of the lipoids from egg yolk. Animals so injected show a relative immunity to acute anaphylactic shock (two minimum lethal doses). Extraction of lipoids contained in antigens increases the toxicity of the antigen when injected into a sensitized animal. Sublethal doses of soap solutions injected simultaneously with the antigen (purified horse serum albumin) prevent anaphylactic shock. The refractory state following anaphylactic shock is related in part to an increase in the antitryptic titer of the serum."

An anomalous strain of Bacillus paratyphosus (B) and its source, H. J. Hutchens and W. J. Tullout (Abs. in Jour. Path. and Bact., 18 (1914), No. 3, pp. 431, 432).—An organism was isolated from brewers' yeast which had been used as a feed for various species of farmyard animals in which it appears to have produced symptoms of acute enteritis. The organism exhibited the usual morphological and biochemical characteristics of the Salmönella group but differed in its agglutination reactions.

Report on the investigation of four cases of sudden death which took place at the Athens State Hospital, E. R. HAYHURST and E. SCOTT (Mo. Bul. Ohio Bd. Health, 4 (1914), No. 10, pp. 1407-1421, fig. 1).—Autopsical findings are presented for four men, patients with minor degrees of psychoses at the Athens State Hospital, and 31, 56, 56, and 67 years old, respectively, who were suddenly asphyxiated within five minutes after entering a new metal silo being filled with corn silage. The men were employed to tramp down the silage, and were waiting for work to begin. In spite of efforts at resuscitation, including hypodermic injections of stimulants, it was impossible to revive any of them.

On the morning following the accident tests were made in the silo with guinea pigs, rabbits, and dogs, which succumbed in a few minutes. About half

an hour later, one of the investigators entered but could detect nothing peculiar until his head was about a foot above the silage, when pungent, warm, slightly alcoholic gas was noticeable. The odor of the gas gave no suggestion of bitter almonds, garlic, or rotten eggs. A second investigator discovered at about 10 in, above the general level of the silage, and from there to the silage the same almost irrespirable gas, which had an immediately irritating effect upon the mucous membrane of the nose, throat, and trachea.

Analysis of a sample of the gas collected from the silo showed carbon dioxid 38.15, oxygen 13.75, and nitrogen 48.1 per cent, while that of a sample obtained from a neighboring silo showed carbon dioxid 0.22, oxygen 20.6, and nitrogen 79.22 per cent. No test was obtained for carbon monoxid, animonia, hydrocyanic acid, or methane.

A crisis in the foot-and-mouth disease situation (*Illinois Sla*, Circ. 178 (1915), pp. 4).—A discussion of the foot-and-mouth disease situation prepared by a committee of the station which emphasizes the fact that it is "the plain duty of all who have the welfare of the live stock interests at heart to unite in supporting the efforts of the federal and state authorities to eradicate the disease from this country."

Immunity against tuberculosis in cattle, A. Calmette and C. Guérin (Ann. Inst. Pasteur, 28 (1914), No. 4, pp. 329-337; abs. in Jour. Compar. Path. and Ther., 27 (1914), No. 3, pp. 263-265).—This is in continuation of work previously reported (E. S. R., 30, p. 482) in regard to determining what part the substances which comprise the bacillus, i. e., the lipoids, the tuberculins, and the bacillary protoplasm, play in the production of immunity.

The lipoids appear to play no part in immunity, and the injection of tuberculin, either crude or precipitated, sensibly retards the development of tuberculosis produced by the test inoculations. The effect of intact bacilli killed by heat and washed was studied for the purpose of determining whether the slight protective power attributed to dead bacilli depends upon the tuberculin inclosed within the bodies of the bacilli.

"An 8-month-old ealf was inoculated intravenously with 20 mg, of bacilliheated for 36 minutes at 65° C, and then washed with salt solution. Threemonths later the animal was tested with tuberculin and gave a very pronounced reaction. It was slaughtered on the same day, and at the post-morten the, lesions of chronic, slowly progressive tuberculosis were found."

"The intact bacillary protoplasm obtained from dead bacilli which are devoid of tuberculin possesses no immunizing action at all. Lasting tolerance possessed by bovines to infection with tuberculosis is due to the presence in their systems of living bacilli. The saprophytic existence of tubercle bacilli in the system leads to the production of soluble immunizing substances different from those obtained in artificial culture media."

The twenty-eight hour law and the animal quarantine laws annotated, compiled by H. Goding (Washington; U. S. Dept. Agr., Office Solicitor, 1915, pp. 52).—An annotation of the act of Congress approved June 29, 1906, commonly known as the "Twenty-eight Hour Law," and the Animal Quarantine Acts of May 29, 1884, February 2, 1903, and March 3, 1905. All of the decisions of the courts contained in the publication of October 2, 1908, entitled "The Twenty-eight Hour Law Annotated," all decisions under the Twenty-eight Hour Law reported since that publication was issued, and all decisions reported under the animal quarantine laws are included.

Sterility in bovines and equines, J. J. Wester (Tijdschr, Vecartscnijk., 41 (1914), No. 1, pp. 13-16; abs. in Vet. Rec., 27 (1914), No. 1362, pp. 109, 110; Cornell Vet., 4 (1915), No. 4, pp. 212, 213).—This article deals with endemic sterility which has been frequently encountered during certain years.

Dehorning cattle, P. V. Ewing (Georgia Sta. Bul. 111 (1914), pp. 193-204, figs. 7).—A popular illustrated account.

The warble flies: Fourth report on experiments and observations as to life history and treatment (Dept. Agr. and Tech. Instr. Ireland Jour., 15 (1914), No. 1, pp. 105-132, pls. 4, figs. 2).—This is a report of investigations, conducted in continuation of those previously noted (E. S. R., 24, p. 61), which have extended up to the summer of 1914.

In the first part of the report New Facts in the Life History (pp. 105-119) are presented by G. H. Carpenter, T. R. Hewitt, and T. K. Reddin.—It is pointed out that while Hypoderma lineatum lays her eggs on the hairs in rows and must, therefore, cling on for a few minutes while depositing them, H. boxis lays her eggs singly and quickly, thus causing the animals to get very excited.—Studies of the external reproductive organs of H. lineatum and H. boxis show that they may be distinguished by very definite structural characters (E. S. R., 31, p. 254).

Up to the summer of 1913 the first-stage larva of the warble fly had not been observed outside the egg, but during that summer it was seen by Gläser in Germany (E. S. R., 32, p. 60) and by the authors in Great Britain. The so-called first-stage maggets mentioned by various authors as found in the gullets of cattle are in reality early second-stage larvae.

"The newly-hatched maggot, though only 0.8 nm, $(\frac{1}{30}$ in.) long, is distinguished by the relatively immense strength of its mouth hooks, and of the spiny armature in transverse rows across its segments especially on the ventral aspect.... The whole aspect of this little larva suggests that it could bore as readily through the skin as through the mucous coat of the gullet. That it does bore into the skin we are convinced as the result of the muzzling experiments and of the direct observations that we have been able to make."

Muzzling experiments indicate that there is no protection from warbles for those calves which can not lick themselves, and confirm the opinion derived from the early muzzling experiments that the maggot usually enters the host's body through the skin. The experiments indicate that the tongue, far from aiding the parasite in its career, rather inhibits its progress and reduces the number of maggots found in animals that can lick themselves. In an experiment conducted during the summer of 1913 three of six calves kept housed and never allowed outside where they would be exposed to warble flies were fed 16 newly-laid *H. bovis* eggs each, the other three being kept as controls. All of the calves failed to develop warbles, thus telling strongly against the view that the parasites gain entrance to the host body by the eggs being licked in.

It is pointed out that the fly deposits its eggs almost exclusively on the legs, not contining itself to any particular part, but showing a decided preference—at least as regards *H. boris*—for the heel or hock joint of the hind limbs. It was observed that a few days after the eggs had been deposited that a soreness appeared in the neighboring region of the skin which was followed by a discharge. "On looking with a lens at the skin near the newly-laid eggs, we saw that it was perforated with minute holes from which flowed a watery discharge, hardening on the surface to form a scaly deposit. After a day or two the region became covered with small pimples which disappeared a few days later. On squeezing the skin of the earliest 'case' that could be obtained, some clear watery fluid exuded from the holes, and on examining a smear of this under the microscope we were delighted to find a newly-hatched magget of *H. lineatum*."

In an experimental attempt to verify these observations the authors clipped closely a small patch on the shoulder of a calf and placed seven maggets thereon. "Immediately they were put on the hairs they crawled down them to the skin and directed their bodies perpendicular to its surface. We soon

found that they were slowly disappearing into the skin, four were lost sight of, but the other three were watched cutting into the epidermis with their mouth hooks and occasionally bending the hinder region of their bodies until they disappeared completely. It took them about six hours to get into the skin; possibly hair follicles may have facilitated entrance. Next morning there were three little eruptions or pimples just where they had entered, and we found four other little pimples indicating where the other maggets which had been lost to view had also bored in. . . These observations confirm the belief deduced from the muzzling results that the maggets enters the animal's body through the skin and not by the mouth and gullet.

"As the eggs are laid on the lower parts of the animals, seldom if ever on the back, and as the maggots, according to our observations, enter the skin somewhat below the position of the eggs, it remains to consider by what course the parasite finds its way to the back." The authors conclude that there is no reason why the maggots should not make their way through the host's body from the skin of the legs to the gullet and thence to the back. After having observed the entrance holes of newly-butched larvae in the skin two cows were slaughtered to trace their further course. A careful search in the skin and the underlying fatty and muscular tissues, however, failed to reveal any maggots. In no case could they be followed further than the superficial layers of the dermis. It is suggested that possibly the minute larva may enter a small vein and be carried in the blood stream, at least part of the way to the gullet.

Examinations were made of a large number of gullets and stomachs of cattle from the Dublin meat markets, and of 1,795 gullets examined 66 contained a total of 625 larvae. The appearance of larvae in the gullet was found to begin in August (on the twenty-sixth in 1914) and the number of affected gullets and of larvæ to increase until November, when the maximum is reached. "In December and January there is a slight decrease in the proportion of affected gullets, but the average maximum of maggets then becomes highest, and it is in these months that the maggets first appear beneath the skin of the back. In February when they become common in the latter position, the number in the gullet shows a marked decrease; in March hardly any are left there (our latest specimen was found on March 14), and from April until July, inclusive, no maggets were found in the gullet at all. These facts altogether support the view that the larvae make their way to the gullet during the late summer and autumn, and leave it during the winter and early spring, traveling toward the region of the spine." The authors' observations indicate that the maggets wander to and fro along the gullet during the late autumn and winter. Seventy stomachs were examined between October 1 and February 28, but no warble larvæ were found in any of them. The authors consider their observation of second-stage larvæ just outside the muscular coat of the gullet, appearing as if they had bored through from the submucous coat, to be a new and most interesting one.

The second part of this paper on The Destruction of Warble Maggots (pp. 119-132) is by J. L. Duncan, T. R. Hewitt, and D. S. Jardine. Systematic destruction by squeezing out the "ripe" maggots has been continued up to the present time, the details relating to which are presented in tabular form.

In the experiments conducted with a view to discovering an effective dressing to be used for maggot destruction, it was found that sulphur dioxid gas applied under pressure to each warble for less than a minute kills 93 per cent of the maggots and causes no harm whatever to cattle.

Eradication of the cattle tick necessary for profitable dairying, J. H. McClain (U. S. Dept. Agr., Farmers' Bul. 639 (1914), pp. 4, figs. 2).—This is a popular account based upon the investigations previously noted (E. S. R., 32,

p. 581), which emphasizes the importance of tick eradication to the dairy industry in the Southern States.

A contribution to the study of the treatment of bovine piroplasmosis by trypanblue, C. Mellis (Rev. Vét. [Tonlouse], 39 (1914). No. 6, pp. 321-334).—Twen(y-three cases of piroplasmosis in different degrees of severity were treated by the author through the use of trypanblue, it being administered subcutaneously in 20 cases in doses of from 100 to 160 gm, of the solution, both with and without pilocarpine, and intravenously in three in doses of 100 gm, with 0.08 gm, of pilocarpine. Nineteen of the cases responded to the treatment. The author points out that with all four animals that succumbed the drug was administered subcutaneously.

A text-book of the topographical anatomy of the horse, W. Ellenberger and H. Baum (Lehrbuch der Topographischen Austomie des Pferdes. Berlin: Paul Parcy, 1914, pp. 1X+427, figs. 215).—This text-book has been prepared from the author's large 3-volume work on the subject (E. S. R., 9, p. 594) for use as a handbook by the veterinary student. The text of this work is shorter than that of the 3-volume work, but the number of figures remains the same, and a large number are in color.

Ophthalmic mallein for the diagnosis of glanders, J. R. MOHLER and A. EIGHIORN (U. S. Dept. Agr. Bul. 166 (1915), pp. 11, pl. 1).—The mallein eye reaction is considered the most appropriate test for the use of the practicing veterinarian for the diagnosis of glanders. The combined agglutination and complement fixation method is considered a good laboratory test, as a check on the field tests and as a last resort in the diagnosis of doubtful reactors.

The ophthalmic test, which is simple to conduct, has been used with much success in Europe, especially in Austria. The reaction commences in from five to six hours after the instillation of the mallein, and lasts from 24 to 36 hours. The essential factor in obtaining satisfactory results is to use the proper kind of mallein. The mallein employed by the Bureau of Animal Industry was in concentrated form (raw mallein) and prepared by the Biochemic Division. The method of preparation is described. Dry mallein may also be used for the test but the solution for instillation must be prepared fresh each day. This form of mallein is used in the State of Pennsylvania for official work. The method of applying and interpreting the mallein test is described in detail and the description is accompanied by a copy of Quarantine Division Form 69, Record of Ophthalmic Mallein Test, used by the Bureau of Animal Industry. The effect of the test on glandered and healthy animals is discussed. Four reproductions of photographs are included to show the varying degrees of reactions.

The report of the special committee of the American Veterinary Medical Association and its conclusions, which are in accord with the findings of the bureau, are presented.

Contagious pneumonia.—Its treatment by neosalvarsan, R. Bunsow (Blood-stock Breeders' Rev., 3 (1914), No. 1, pp. 40-43; abs. in Vet. Rec., 27 (1914), No. 1358, pp. 47, 48).—This article calls attention to the recent advances made in the treatment of pectoral influenza of equines through the use of neosalvarsan, which has much the same properties as salvarsan (dioxydiamidoarsenobenzol).

Hog cholera as a result of vaccinating against erysipelas, Müller (Berlin, Tierärztl, Wchuschr., 30 (1914). No. 13, Beilage, pp. 21-24).—A culture of erysipelas bacteria suspected of being the cause of hog cholera was tested upon 7-to 8-week-old shoats. Some were given the culture and others the filtrate from the culture, while another lot received blood serum, filtered and unfiltered, and organ pastes from affected animals.

The animals receiving the filtered and untiltered cultures became affected with hog cholera, but the others did not. A number of the pigs which remained sound and some controls were fed with organs from the pigs which died from hog cholera and as a result of treatment with erysipelas culture, and others were placed in the infected stable. In both instances the animals became affected with hog cholera. The symptoms and pathological findings are briefly stated.

The curative action of autolyzed yeast against avian polyneuritis, E. A. Coofer (Biochem, Jour., 8 (1914), No. 3, pp. 250-252).—" By the autolysis of brewers' yeast a solution can be obtained which possesses as marked curative properties toward avian polyneuritis as the original yeast. The solution retains its curative power for at least eight weeks and when given orally to birds in doses ten times as great as the minimum curing dose has no toxic action. Airdried yeast retains its curative power after storage for two years in a dry tin, and still autolyzes after storage for four months."

House disinfection with formaldehyde, W. Löwenstein (Ztschr. Hyg. u. Infektionskrank., 78 (1914), No. 2, pp. 363-384).—When formaldehyde was used for disinfection in the neighborhood of heated bodies the bacteria were killed with difficulty. Moist test objects were killed quicker than dry substances. Threads dipped in and saturated with bouillon cultures were more resistant to formaldehyde disinfection than agar cultures suspended in water. Formaldehyde acted in a similar manner on moist and dried bouillon culture test objects.

RURAL ENGINEERING.

Some measuring devices used in the delivery of irrigation water (California 81a, Bul. 247 (1915), pp. 111–180, pl. 1, figs. 31).—This bulletin, prepared under a cooperative agreement between the Irrigation Investigations of this Office and the University of California, describes the testing station at Davis, Cal., which is used for the purpose of examining, testing, and demonstrating the principal irrigation water measuring devices so far developed, and describes, illustrates, and points out the relative accuracy of some of the devices that have already become standard or that have been in use for a sufficiently long time or on a sufficient scale to warrant their installation at the laboratory.

Three measuring hydrants for underground distribution systems were tested. The Azusa hydrant provides for measurement through one or more oritices on the center of which a pressure head of 4 in, is maintained by means of a sheet iron spill crest set at right angles to the orifice plate. The hydrant is in the form of a concrete box placed over the supply pipe line and the area of the openings in the orifice varies from 10 to 50 sq. in. The average of all tests made on this hydrant showed "the amounts in inches being carried through the openings to be 1 per cent more than their area in square inches," including all errors in measurements. All openings or combinations of openings were equally accurate. It is thought, therefore, that the box will measure as accurately as is required.

The Gage hydrant consists of a main box of 2-in, mortar, the bottom of which is cast separately and the top cemented to it in the field. The weir crest consists of \(\frac{1}{8}\)-in, by 1\(\frac{1}{2}\)-in, iron cemented to the sides, giving a final opening of 10 in, wide and 10\(\frac{1}{2}\) in, high. In the tests of this hydrant it was found that the amount of water discharged for any given depth was greater than with a standard 10 in, weir, owing to the nearness of the sides of the box to the sides of the weir and to the velocity conditions in the box. "The amount of this difference increases as the head increases, being as much as 35 per cent at the

higher heads." It is stated that the principal source of error in using this box in practice will be the difficulty in measuring the depth over the weir closely.

The Riverside box consists of a shallow box set over the end of the delivery pipe line. The water enters through the bottom of the box and is measured out through an adjustable cast-iron measuring plate in the end. In tests of this device the average difference between the number of inches actually received and the area in square inches of the opening was about 2 per cent. For all tests the area in square inches of the opening averaged 1 per cent greater than the inches actually received. It is thought that where care is used to adjust the width of the opening to the amount running this box will measure water very closely.

In tests of the Foote inch box the amount of water supposed to have been passed averaged 4 per cent greater than was actually run and the error did not vary with the amount of discharge. "From these tests it appears that the slide can be set within an average 4 per cent of correct if care is used. This box will measure water up to 150 in, satisfactorily under conditions to which it is adapted, although it is not in general an economical box to use."

A general discussion of different types of weirs in use is given, including weir tables which are in general use.

Submerged oritices are also described and tables developed by the U. S. Reclamation Service for determining their flow under different conditions are given. Tests of a submerged oritice 2 ft, wide and ½ ft, high gave a coefficient of 0.61 which agrees with that determined by the Reclamation Service. In tests of a submerged oritice gate under two conditions it was found that the mean of all measurements using the level board gave a mean coefficient of 0.8 while the measurements on the gate gave a mean of 0.72. "From these results it is seen that the coefficient for such measuring gates varies with the type of gate. . . . Where the lack of sufficient fall for the use of a better measuring device makes the use of this type of submerged orifice necessary, a standard size and structure should be adopted, and special discharge tables prepared. This should then be rated under the condition in which it will be used."

Three mechanical devices for measuring and registering the total flow were tested. The Dethridge meter consists of a wheel or drum to which projecting pieces of sheet metal are fastened. The drum is placed with its axle horizontal and is so set that the projecting blades are in the current of the ditch to be measured. Λ special box is built around the wheel so that all water in passing has to strike against the blades. The tests of this device showed the meter to be quite accurate under constant ditch conditions between rates of flow of from 1 to 3.5 second-feet. For both larger and smaller discharges the meter passed more water than it did between these limits. "The amount of water going through the meter varies with the depth of drowning. A meter set high in the ditch will discharge less water per revolution than one set low. Checking up the ditch below a meter so that the depth is increased at the meter may increase the discharge by as much as 10 per cent in some cases. . . . The Dethridge meter of this size is adapted for accurate measurement of streams varying from 1 to 3 or 4 cu. ft. per second."

The Grant-Michell meter consists of a wheel turning in a horizontal circular opening through which the water is made to pass. The meter consists of four flat blades set so that the water in flowing through the circular opening strikes against them at an angle. On the upper end of the shaft carrying the wheel is a counter which records the number of revolutions of the wheel. Tests made of the 21-in, meter showed that for discharges of over 2 second-feet and up to 6.5 second-feet the meter makes one revolution for every 6.1 cubic feet of

water passed. More water is passed per revolution on lower rates of discharge. The tests show that the meter will probably register within 2.5 per cent of the true quantity. The fall required in the ditch varies with the rate of flow from about 1 in, for a discharge of 3 second-feet to 4 in, for a discharge of 5 second-feet. The high cost of this meter is said to be against its general use.

The Hill meter consists of a circular horizontal opening in the floor of a box through which the water to be measured is made to pass. The meter consists of curved vanes on a central drum. H sits in the center of the opening and is turned by the water as it strikes against the vanes on rising through the open-The turning of the meter drives the gears of a counting device which records the water passed in acre-feet. Tests of a 12-in, Hill meter showed that this size of meter apparently registers the quantity passed within 1.5 per cent for discharges of from 1 to 3.5 second-feet. For discharges of less than 1 secondfoot more water passed the meter than was registered and for discharges of 3.5 second-feet the water beiled up through the opening so as to submerge the counter. The loss of head of fall in the water required for this meter varied from 1 in, when carrying 1 second-foot to $6\frac{1}{2}$ in, when carrying 3.5 second-feet. "The Hill meter seems adapted to use under the usual conditions of irrigation practice. It is simple and has few wearing parts. The head required for the different sizes is less than that needed for the use of weirs. The record of the total quantity of water passed can be read in units of 0.001 acre-foot,"

The data of the tests are given in an appendix.

Stream gaging by titration: Comparative tests of new chemical and standard mechanical methods of gaging stream flow, L. W. Collet et M., trans. by G. Blaauw and R. E. Ward (Engin. and Contract., 42 (1914), No. 12, pp. 270–273, figs. 3).—This article explains the method of stream gaging by chemical means, describes the preparation of the solution, and the computation of results.

The process is based on the theory that if a constant quantity of concentrated solution of sodium clorid be injected into a stream and samples of water taken at a certain distance from the point of injection into the stream, the discharge may be determined by the fact that the ratio of the discharge of the initial solution to the discharge of the final solution is inversely proportional to the ratio of their concentration. The conditions necessary for the success of this method of gaging are (1) a constant rate of flow of the initial solution, (2) perfect mixing, and (3) accurate titration of the salt solution,

Comparative tests made in Switzerland of the chemical method with the current meter, curtain, and weir methods are described, from which it is concluded that the titration method is rapid and exact, permits the easy determination of a discharge of high head turbines, is applicable in certain cases to test low head turbines, and may be used in gaging Alpine streams where other methods are considered inaccurate.

The hydraulies of irrigation, drainage, and other channels, L. Schmeer (Engin. and Contract., 42 (1914), No. 13, pp. 284-290, figs. 4).—The author briefly reviews the history of channel flow formulas, deduces an equation for circular conduits running full, discusses the practical application of formulas for conduits under pressure, and deals in more or less detait with formulas governing the flow of water in open conduits, covered aqueducts, and egg-shaped conduits.

Ground-water supplies, O. Smerker (Das Grundwasser, Seine Erscheinungsformen, Bewegungsgesetze, und Mengenbestimmung. Leipsie: W. Engelmann, 1914, pp. 67, figs. 27; rev. in Engin. News, 72 (1914), No. 21, p. 1046).—This book is divided into seven sections which embrace a review of the principal

theories of the formation of ground water, the interchange of surface and subsoil waters, the law of resistance to the motion of water through the ground, the efficiency of different methods of obtaining a water supply, the determination of the shape of the cone of depression of the ground-water surface by means of experiments with pumps, and the determination of the discharge of a stream of ground water through a given basin or cross section.

Economic factors involved in road construction in strictly rural sections (Engin, and Contract., 42 (1914), No. 11, pp. 255-258).—This article considers the economics of country road construction from the standpoint of the general welfare of the community, discusses the relative permanence of construction and structural details, and describes methods of financing.

It is considered fundamental that any outlay of money be made in such a manner that it will result in a paying investment to the community. With this in view it is concluded (1) that no road should be improved without some provision for its maintenance, (2) that all improfitable work and works "de luxe" be avoided within certain limits, (3) that all improvements not actually and positively needed be omitted or postponed, (4) that the choice of kinds of pavement the durability and ease of maintenanc of which have not been ascertained

in practice be avoided as much as possible, and (5) that unnecessary experi-

ments be avoided.

The relation of farm produce hauling to permanent road improvements (Engin. and Contract., 42 (1914), No. 9, pp. 215-217, figs. 2).—This article discusses economic questions relating to the classification of highways, hauling radius, apportioning of aid, supporting areas of cities, and cost of distributing food products, treating these subjects as fundamentals to economic road design under Ontario, Canada, conditions.

Concrete highway bridge construction as standardized by Iowa commission, C. B. McCullovan (Engin. Rec., 70 (1914), No. 19, pp. 514-517, figs. 6).—The author, in describing the process by which the Iowa Highway Commission has arrived at its standards for concrete highway bridges, states that topographical conditions markedly influenced the selection of designs for different parts of the State.

The cantilever type of abutment has been chosen for the general standard, but to meet conditions of searcity of concrete materials in the Kansan drift area the pedestal or integral approach span type is being developed. The box type of culvert is said to have proved in general the solution of the culvert problem except in cases of very deep ravines requiring excessive fill, when the arch culvert is used.

Specifications and permissible stresses in material are given, and the standard superstructure plans were designed for the following loadings: (1) Dead loadings of earth fill at 120, concrete at 150, and brick masonry at 150 lbs. per cubic foot; treated timber at 5 and untreated timber at 3½ lbs. per foot, board measure; and (2) a uniformly distributed live load over floor and sidewalk surface of 100 lbs, per square foot or a concentrated live load consisting of a 15-ton traction engine with weight on the rear axle of 20,000 lbs, and on the front axle of 10,000 lbs., distance between axles 11 ft., distance between the rear wheels 6 ft., and width of the rear wheels 22 in. "Where the floor slab supporting this concentration is relatively thin, as in the deck girder floors, each of the rear wheels is assumed to distribute over an area 4 by 4 ft. Where the slab is 12 in, thick or over the lateral distribution is increased to 6 ft. for each wheel or 12 ft. for the entire rear axle load, and the longitudinal distribution is taken as 5 ft. The culvert loadings are taken the same as the foregoing with the addition that below 1 ft. the wheel load concentration is assumed to distribute through the earth fill in four directions at the rate of ½ horizontal to 1 vertical." The details of the designs of various standard structures, including deck and through girders, are further discussed.

Notes on using kerosene, J. A. King (*lowa Engineer*, 15 (1914), No. 2, pp. 56–58).—The author concludes that the best results are obtained today with kerosene as a fuel for internal combustion engines when one uses a theroughly efficient carburctor in connection with a water spray and on a throttle-governed engine.

Dynamics of a plow, J. Keir (Jour, Agr. [New Zeal.], 8 (1914), No. 6, pp. 597-606, figs. 12).—The author, in endeavoring to explain the dynamics of a plow, deals with the single furrow lever plow of the New Zealand type having three wheels. He points out in conclusion that a great deal of misapprehension regarding the relative draft of light and heavy plows exists among farmers and plowmen. The draft of plows running on wheels on level land, he states, is not appreciably affected by the dead weight of the plow. "The draft of every plow is almost entirely due to the work done on the furrow, and will vary with the width and depth of furrow, and condition and quality of the land. While a light plow is easier to handle for the man, within reasonable limits and on level land, it makes hardly any difference to the horses."

The strength and design of washers in reference to the bearing on wood, L. R. Rodenhiser (Cornell Cir. Engin., 23 (1914), No. 2, pp. 41-45, figs. 6).—
Investigations are reported with four different types of structural timber to determine (1) the safe bearing value and ultimate strengths of different woods under different washers, and (2) the economic size of washers in order to make the safe bearing value and ultimate strengths as high as possible and yet keep the weight of the washers down to a minimum. The main conclusions reached are as follows:

For bolts of less than $\frac{1}{2}$ -in, in diameter no reinforcement of the washer is necessary, a flat plate large enough to provide sufficient bearing area being all that is required. For each inch of diameter of the plate there should be $\frac{3}{16}$ in, in height and $\frac{1}{16}$ in, in thickness for the spool, but no spool should be less than $\frac{1}{4}$ in, in height or less than $\frac{3}{16}$ in, in thickness.

Silo construction, P. V. Ewing (Georgia Sta. Bul. 110 (1914), pp. 165-176, figs. 8).—This section gives general information regarding the size and construction of silos.

Housing in rural districts, E. Holloway (Surreyor, 46 (1914), No. 1182, pp. 330, 331, figs. 4).—The type of rural cottage decided on for the Evesham and Pebworth rural districts of England is described and diagrammatically illustrated. It is one having a large living room and a small scullery on the first floor, and three bedrooms on the second floor, two of which have fireplaces.

The construction of the cottages is as follows: Outside and party walls are of 9-in, brickwork, internal walls on the ground floor 4½-in, brickwork, and on the second floor 2-in, concrete partition slabs. The roofs are tiled, and have a pitch of 45°. In one case rough-cast has been used for the exterior walls. The floors of the living room are 6-in, square tiles laid on 4-in, cement concrete, and in the scullery and elsewhere on the ground floor granolithic floors have been laid; upstairs, 1-in, best white flooring with matched edges is used, the timber being red deal throughout; the plastering on the ceilings is three-coat work, and on the walls two coats. In every instance casement windows are put in, and ample provision is made both for light and ventilation. The height of all rooms is 8 ft. throughout.

Rural laborers' cottages (Surveyor, 46 (1914), No. 1180, pp. 272-277, figs. 21).—A quadruple system of rural housing, each house of which is said to cost not over £152 (\$739.70), is described and diagrammatically illustrated.

Some of the main features of these cottages are as follows: (1) The entrance gives access by a straight stairway direct to the upper rooms, (2) the living room, while directly accessible from the front door, stairs, and scullery, gives the maximum of floor space free of traffic and a fireside away from drafts, (3) all chimneys are on inside walls, (4) all bed spaces are against inner walls while their positions afford the maximum amount of unimpeded floor space, (5) a bath space is available if desired, (6) three sides of each of the apper bedrooms have solid brick walls, and (7) the upper internal walls are natural continuations of those below, there being no partition work.

RURAL ECONOMICS.

The cost of producing Minnesota farm products, 1908–1912, F. W. Peck (Minnesoto Sta. Bul. 145 (1914), pp. 48, figs. 6).—Continuing previous work (E. S. R., 23, p. 695; 26, p. 474), this report is based upon a study of a number of farms located at Northfield, Marshall, and Halstad, Minn. The report describes the methods of collecting and compiling the statistics, the climatic conditions, average crop yields, and average farm prices, and discusses the various factors used in computing the cost of farm crops and the acre as a basis of comparison.

Among the principal results noted were that the average monthly cost of board per man at Northfield amounted to \$15.43; at Marshall, \$14.17; and at Halstad, \$12.36. The average rate of wages per hour for the eight crop-season months was \$0.149 at Northfield; \$0.139 at Marshall; and \$0.135 at Halstad. The average annual cost of maintaining a farm work horse at Northfield was \$103.41; at Marshall, \$99.67; and at Halstad, \$84.16. The average cost of horse labor per hour worked amounted to 10.1 cts, at Northfield, 9.01 cts, at Marshall, and 8.63 at Halstad. The average annual depreciation of machinery amounted to 6.7 per cent. The annual values consumed per acre (depreciation, labor, cash repairs, and interest) for the commonly used machines were grain binders, 16.8 cts.; grain drills, 7.2 cts.; corn binders, 60.4 cts.; wagons, 19.5 cts.; mowers, 16.7 cts.; and plows, 9.5 cts.

The total cost of producing an acre of spring wheat was reported as \$10.78; oats, \$12.02; barley, \$11.16; flax, \$10.70; potatoes, \$52.18; corn, cut, shocked, and hauled from the field, \$14.75; corn, husked from standing stalks, \$14.52; fodder corn, stacked at the farmstead, \$14.84; clover and timothy, first crop. \$7.51; wild hay, \$7.30. The bulletin also shows the average cost of plowing at different seasons of the year, and other cost data.

The report contains a number of statistical tables showing complete details.

Statistics of cooperation among farmers in Minnesota, 1913, L. D. H. Weld (Minnesota Sta, Bul. 146 (1914), pp. 22, jigs. 8).—This bulletin indicates that there were 2,013 cooperative organizations in Minnesota on January 1, 1914, and that the annual volume of their business during the previous year was \$60,760,000. Of this number 614 were creameries doing a business of \$21,675,-252, 600 telephone companies with a business of \$900,000, and 270 elevators with a business of \$24,000,000. This bulletin describes the most important features found among the cooperative creameries and cheese factories, farmers' elevators, live stock shipping associations, telephone companies, and insurance companies.

The New York State Vegetable Growers' Association (N. Y. State Veg. Growers' Assoc. Rpt. 1913-14, pp. 286, pl. 1, figs. 5).—This report contains a series of addresses relating to the production, distribution, canning, and storing of vegetables.

Report of the public roads and highways commission of Contario, 1914 (Rpt. Pub. Roads and Highways Com. Ontario, 1914, pp. 277, pls. 16, figs. 16).—This report discusses the development of highways in Ontario, Canada, and its

influence upon the agricultural production and the marketing of agricultural products, and outlines certain factors to be considered in their future development.

Rules and regulations of the Secretary of Agriculture under the United States Cotton Futures Act of August 18, 1914 (U. S. Depl. Agr., Office Sec. Circ. 46 (1915), pp. 24).—This circular contains the definitions, rules, and regulations of the Secretary of Agriculture under the United States Cotton Futures Act, which taxes contracts of sale of cotton for future delivery not made in accordance with its provisions. The text of the act is appended.

[Amendment, United States Cotton Futures Act] (U. S. Dept. Agr., Office Sec. Cive. 46 (1915), Amends. 1, p. 1; 2, p. 1).—These (we amendments relate to the elimination of Waco, Tex., and Fall River, Mass., from among the list of "spot markets."

Government crop reports (*U. 8. Dept. Agr., Buv. Crop Estimates Circ. 17. rev.* (1915), pp. 27).—This circular discusses the origin, value, scope, method, and bases of the crop estimates and gives a table showing the scope of work involved in the preparation of the several crop reports by months, and the details involved in making the final estimates.

Statistical atlas of the United States, 1914 (Bur. of the Census [U, 8.], Statis, Atlas U, 8., 1914, pp. 99+XII, pls. 503).—This volume contains maps and diagrams to illustrate the statistical tables of the Thirteenth Census, and includes diagrams and maps relating to rural population, agriculture, manufacturing, and those gainfully employed.

Annual statistics of Chile (An. Estad. Chile, 10 (1912–13), pp. 221).—This volume contains statistical data showing the area and production of the principal agricultural products and the number of live stock by provinces.

Report on the agriculture of Saxony for 1913 (Jahresber, Landw. Könige, Sachs., 1913, pp. 171+343).—This report gives information concerning agricultural credit, labor, trade, and education, and the inspection of foodstuffs, fertilizers, and seeds, the cultivation of land, animal industries, and live stock sanitation.

AGRICULTURAL EDUCATION.

Proceedings of the Conference on Rural Education, February 10, 1913 (Proc. Conf. Rural Ed. [Mass.], 1913, pp. 45).—Among the papers and addresses included in the proceedings of this conference are the following: Rural Education from the Standpoint of the Agricultural College and Teacher, by W. R. Hart; Rural Education from the Standpoint of the Rural Citizen, Taxpayer, and Parent, by E. E. Chapman; The Betterment of Rural Schools, by E. T. Fairchild; Educational Possibilities in the Rural High School, by R. W. Stimson; Educational Possibilities of Improved Social Conditions, by H. N. Loomis; Two Types of Agricultural Education, by D. Snedden; and Needs and Possibilities of Education in Rural Communities, by P. P. Claxton.

Present status of agricultural education in Canada, S. B. McCready (Internat. Inst. Agr. [Rôme], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 5, pp. 571-578).—The author gives an account of the jurisdiction of the federal and provincial governments, the agricultural instruction act of 1913, and the present organization of agricultural instruction in the various Provinces of the Dominion.

Annual report of the state director of industrial education to the superintendent of public instruction, Manette A. Myers (Ann. Rpt. State Dir. Indus. Ed. [N. Mex.], 1913, pp. 152, figs. 70).—This report contains (1) a copy of the act approved June 10, 1912, empowering the New Mexico board of education to prescribe a course in industrial education, including agriculture,

domestic science, and manual training for the public schools, and to appoint a state director of industrial education, and of the 1912 county high school law, providing that manual training and domestic science, agriculture, and commercial science shall be added to the course of county high schools; (2) brief reports on the first and second contest of the boys' and girls' industrial club in 1912–13, and plans for farm crops, poultry, and housekeepers' contests for 1914; and (3) notes on agricultural and domestic science instruction in the various counties of the State.

Vocational schools, A. D. Dean (Univ. State N. Y. But. 566 (1914), pp. 76).—The author discusses the operation, spirit, and purpose of the law giving state aid to vocational schools; the principles underlying state aid; the meaning and controlling purposes of vocational education; the rules and regulations of the commissioner of education covering organization, courses of study, and content of instruction; the five types of vocational schools, including the schools of agriculture, mechanic arts, and home making; a description of the progress of agricultural teaching in the Hancock High School as an illustration of the viewpoint of the community toward this work and of difficulties to be overcome; part-time or continuation schools and evening vocational schools in which instruction is given in the trades and in industrial, agricultural, and home economics subjects; the training of teachers for vocational subjects; and the movement for vocational guidance. Typical agricultural, industrial, and drawing programs are given for use of state conferences of teachers, principals, and supervisors engaged in vocational instruction in state-aided schools.

Elementary science courses, Ora M. Carrol (Nature-Study Rev., 10 (1914), No. 7, pp. 253-260),—This is a discussion of the present status of instruction in nature study in normal schools, mainly in the Middle West, and in agricultural colleges and universities.

The teaching of agriculture in the high school, J. G. HICKOX (Ohio Teacher, 35 (1914), No. 4, pp. 151, 152).—The author briefly discusses the aim of instruction in agriculture, in what schools it shall be offered, what pupils shall study it, the length and content of the course, laboratory work, and apparatus.

Should normal schools offer a special course for the training of rural school teachers? A. E. Maltry (Proc. Bd. Princ. State Normal Schools Penn., 1913, pp. 4-12).—In this paper the author discusses the necessity of increasing the efficiency of the rural school by bringing it into closer touch with the life of the people, their work, and their interests. In his opinion the rural school under a teacher properly prepared for the work may become a center that will influence every farm and home in the district, hence the normal school should train teachers in agriculture and other rural arts as well as household and manual arts. The work in agriculture should embrace text-book study, reference work, lectures, demonstrations, laboratory experiments, observation of field work, planting and care of school gardens, etc. A certain area of the school ground should be set aside for field work, and poultry yards with necessary equipment might be established, as well as an orchard for demonstration purposes. Two outlines are given of suggested 2-year courses for rural teachers.

Home economics in the agricultural college, Jessie M. Hoover (*Jour. Home Econ.*, 4 (1912), No. 2, pp. 150–155).—The author gives an account of what the home economics departments of agricultural colleges are doing to give instruction in home economics by means of regular courses and extension work.

Home economics extension work in Kansas, Mary P. Van Zile (Jour. Home Econ., 4 (1912), No. 2, pp. 155-158).—An account is given of the extension work in home economics conducted by the Kansas College, including the women's auxiliary to farmers' institutes, girls' home economics clubs, movable schools, correspondence courses, and state farmers' institutes.

The extension work of the College of Hawaii, V. MacCaugney (Col. Hawaii Circ, 3 (1914), pp. 30).—An account is given of the object and organization of the extension work of the College of Hawaii.

Agricultural and household science extension schools and community federations, A. W. Nolan and R. E. Hilliannymus (Agr. Col. Ext. Univ. III., Form 27 (1914), pp. 14, figs. 4).—The authors give a description of the organization and work of agricultural and household science extension schools, including typical programs conducted by the College of Agriculture of the University of Illinois, together with suggestive topics and an outline of a constitution for community federations.

Extension work in Minnesota, MARY L. BULL (Jour. Home Econ., 4 (1912), No. 2, pp. 159-161).—The home economics extension work of the University of Minnesota is described.

Social and civic work in country communities, Ellin B. McDonald, Rosa M. Cheney, G. F. Comings, and W. E. Larson ([Wis. State Supt. Pub. Instr.] Bul. 18 (1913), pp. 138, figs. 20).—In this bulletin a subcommittee of a committee of 15, appointed by the state superintendent of schools to investigate conditions in the rural schools of Wisconsin, endeavors to show the part the home, the school, and the people must take in social and civic work in country communities. Concrete suggestions are presented for special school and social programs, for the organization for intellectual development of young people who no longer attend school, for gatherings for older people, for the training of teachers for social and civic improvement work, for the organization of permanent clubs for the betterment of home, civic and social, industrial and economic, and educational conditions, and for the federation of these organizations, and an account is given of what Wisconsin is doing for social and civic improvement in rural communities. An article on Farmers' Organizations in the Past, by George Wehrwein, and appendixes on school industrial credit for home industrial work, a suggested constitution for a neighborhood improvement club, and a list of references for teachers and others interested in country life improvement, are included.

Instruction trains (Agr. Gaz. Canada, 1 (1914), No. 9, pp. 712-729, figs. 5).— This is a symposium on the methods and experiences of the Provinces of New Brunswick, Quebec. Ontario, Manitoba. Saskatchewan, and Alberta, with "better farming specials."

The Los Angeles nature-study exhibition, C. I. EDWARDS (Nature-Study Rev., 10 (1914), No. 7, pp. 263-270, figs. 5).—This is a description of the second annual nature-study exhibition of the Los Angeles city schools, held June 6.

New course of study (Neuer Lehrplan, Proskau, Germany: Königl, Lehranst, Obst. u. Gartenbau, 1914, pp. 27).—This is an outline and description of the new 2-year course of study, including a schedule of hours, of the Royal Institute for Pomological and Horticultural Instruction in Proskan.

Pre-vocational agricultural work in the public schools of Indiana (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 8 (1914), pp. 31).—The purpose of this bulletin is to give suggestions on what the schools are expected to do in pre-vocational agricultural work and how the work should be done in 1914–15, by means of type studies based on the state course of study in agriculture. Lists of agricultural books and apparatus for the seventh and eighth and high school grades are included.

[Rural school agriculture] (Rural School Agr. [Univ. Minn.], 2 (1913), Nos. 5, pp. 4, fig. 1; 6, pp. 4, fig. 1; 7, pp. 4, fig. 1; 8, pp. 4, fig. 1; 9, pp. 4, fig. 1; 3 (1913), Nos. 1, pp. 4, fig. 1; 2, pp. 4, fig. 1; 3, pp. 4, fig. 1; Sup. pp. 4; 4, pp. 8, figs. 5; 3 (1914), Nos. 5, pp. 8, figs. 7; 6, pp. 8, figs. 5; 7, pp. 8, figs. 2; 8, pp. 8, figs. 2; 4 (1914), Nos. 1, pp. 8, figs. 2; 2, pp. 8, figs. 2).—These circulars treat in

monthly sequence of the study of corn, poultry, nature study, the organization of boys' and girls' clubs, dairy eattle, farmers' clubs and cooperation, farm horses, bread making, sewing, cooking, swine, the acre yield corn contest for 1914, bread making contests, planning a garden, outlines of work for 1914 and 1915, and warm lunches for rural schools.

Elements of forestry, F. F. Moon and N. C. Brown (New York; John Wiley & Sons, 1914, pp. X111+392, figs. 65).—This general text-book on forestry defines and explains forestry, and discusses its need in the United States and its development here and abroad; the tree, its parts, functions, characteristics, growth, etc.; silvics; silvicultural systems of management; improvement cuttings; artificial regeneration; forest protection and mensuration; lumbering; wood utilizations, technology, and preservation; and forest economics and finance, followed by regional studies. An appendix gives the original and present forest areas in the United States, uses of the principal American species, log rules, etc., and a glossary of terms in forestry and logging.

Helps for domestic science work in seventh and eighth grades, September-October (Dept. Pub. Instr. [Ind.], Ed. Pubs., But. 13 (1914), pp. 25).—Suggestions are given to village and rural teachers for introducing and carrying on domestic science work, and lessons are outlined for each week in the months of September and October in cooking and the study of foods, sewing and the study of clothing and textiles, and shelter, including projects and problems relating to home and personal hygiene, care of the home, home furnishing, decoration, etc.

Shumway agricultural high schools: Suggestions for laying out and planting the school farm (Lincoln, Nebr.; Dept. Pub. Instr., 1914, pp. 23, figs. 2).—Suggestions are given for laying out and planting the 5-acre farms secured by the high schools giving instruction in agriculture under the Shumway Act. The plans are considered under the main headings of fertilizer contests, crop rotations, continuous cropping, a crop museum, a few simple tests with crops, cultural field studies, the orchard, the family garden, and pathological demonstrations.

Some experiments for the garden, J. W. Emery (Nature-Study Rev., 10 (1914), No. 7, pp. 281-287).—According to the author an endeavor is being made in Ontario to meet the chief obstacles to successful school gardening—scarcity of land, neglect during the long summer holidays, lack of broad knowledge on the part of the teacher, and apathy or even active opposition on the part of the trustees and parents—with home gardening, summer courses for teachers, and the sending out of capable young men from the agricultural college to visit every rural section, enlist the sympathies of the parents, and give the teacher a start in the work. The economic side of school gardening is to be emphasized. and in this way it is hoped to find the solution to the problem of rural depopulation. The advantages of the introduction of systematic experimental work as a sort of compromise between the purely cultural and the purely agricultural aims of nature study are enumerated, and experiments outlined which have been found to work out successfully in the neighborhood of the normal school at Stratford, Ontario, and which are deemed possible in the poorest equipped school.

Should school gardens be made to show financial gains? E. S. Sell (Nature-Study Rev., 10 (1914), No. 7, pp. 273-275).—The author calls attention to an experiment he is making at the State Normal School at Athens, Ga., to test the theory that gardens should be run in such a manner as to show financial gains when possible. He maintains that it has been demonstrated "that a school garden can be made to better serve the purpose when records are kept that

involve the profits and losses." This method creates an increased interest by students in the garden work and seems to vitalize and make it more of a definite problem.

Nature study and school gardens, II. Findlay (Bul. N. Y. State School Agr. Morrisville [1917], pp. 7).—This bulletin points out the value of nature study and offers suggestions on making gardens and caring for them.

Suggestions and regulations on the work of corn clubs, J. F. EASTMAN (Bul. N. Y. State School Agr. Morrisville [1914], $\hat{p}p$, 8).—This bulletin contains reasons why boys and girls of the rural schools should be helped to form clubs or other organizations for studying agriculture and improving the farm practice of their community, a suggested model club constitution, and directions for corn culture.

MISCELLANEOUS.

Twenty-seventh Annual Report of Indiana Station, 1914 (Indiana Stat. Rpt. 1914, pp. 88, figs. 2).—This contains the organization list, reports of the director and heads of departments, the experimental features of which are for the most part abstracted elsewhere in this issue, and a financial statement for the state funds for the fiscal year ended September 30, 1914, and for the remaining funds for the fiscal year ended June 30, 1914.

Twenty-seventh Annual Report of Michigan Station, 1914 (Michigan Sta. Rpt. 1914, pp. 199-559, pl. 1. figs. 107).—This contains reports of the director and heads of departments on the work of the station during the year, the experimental features of which are for the most part abstracted elsewhere in this issue; a financial statement for the tiscal year ended June 30, 1914; and reprints of Bulletins 272 and 273, Special Bulletins 62-71. Technical Bulletins 18 and 19, and Circulars 21-23, all of which have been previously noted, and of Circular 24, abstracted elsewhere in this issue.

Twenty-fifth Annual Report of New Mexico Station, 1914 (New Mexico Sta, Rpt. 1914, pp. 85, figs. 6).—This contains the organization list, a report of the director on the work, publications, and exchanges of the station, including reports of heads of departments, the experimental features of which have been for the most part previously noted or abstracted elsewhere in this issue, and a financial statement for the fiscal year ended June 30, 1914.

Thirty-second Annual Report of New York State Station, 1913 (New York State Stat. Rpt. 1913, pp. 814, pls. 33, figs. 54).—This contains the organization list; a financial statement as to the federal funds for the fiscal year ended June 30, 1913, and as to the state funds for the fiscal year ended September 30, 1913; reprints of Bulletins 357–372. Technical Bulletins 27–31, Circulars 20–25, and popular editions of Bulletins 357–359, 361–365, 367, 368 and 369, and 370, all of which have been previously noted; a list of the periodicals received by the station; and meteorological observations noted on page 614 of this issue.

Farmers' Day guide (Delaware Sta. Circs. 7 (1912), pp. 26; 8 (1913), pp. 26; 9 (1914), pp. 26).—These circulars, prepared for distribution at the annual Farmers' Day, furnish a key to the experimental plats and live stock in June, 1912, 1913, and 1914, respectively.

Laws applicable to the United States Department of Agriculture, compiled by O. H. Gates (Washington: U. S. Dept. Agr., Office Solicitor, 1915, 2. Sup., pp. 128).—This publication represents a revision of that previously noted (E. S. R., 29, p. 899), embracing legislation enacted from August 28, 1912, to October 24, 1914, inclusive.

NOTES.

Alabama College and Station.—Dr. F. L. Thomas has been appointed assistant professor of entomology and assistant entomologist. E. A. Vaughan has succeeded G. W. Ells as field assistant in entomology.

Arkansas University and Station.—The extension service of the college of agriculture has been much developed during the last two years and has brought the institution before the people of the State to a degree not obtained heretofore. Calls for information through correspondence alone have at least doubled in the last six months.

New appointments in the board of trustees include J. K. Mahoney, vice W. H. Askew, deceased; Z. L. Reagan, of Fayetteville, vice Dr. Charles Richardson; and J. K. Browning, of Piggott, vice T. A. Turner.

Hawaiian Sugar Planters' Station.—Paul 8. Burgess, assistant professor of soil bacteriology at the University of California and assistant soil bacteriologist in the station, has been appointed chemist, succeeding 8, 8, Peck, resigned.

Idaho University and Station.—Dr. M. A. Brannon has tendered his resignation as president. E. J. Iddings, vice dean of the college of agriculture and animal husbandman, has been appointed dean of the college of agriculture. J. S. Jones has been appointed director of the station.

The legislature has discontinued appropriations formerly given for extension work, granting only an amount sufficient to meet the Smith-Lever increases.

Iowa College and Station.—The department of chemistry has occupied the new building which replaces that destroyed by fire about two years ago. The new building is a three-story and basement structure, 244 by 162 ft., of brick, stone, and concrete, and cost about \$200,000.

Dr. P. L. Blumenthal has resigned as assistant chemist in the station to take effect June 1.

Maine Station.—Recent appointments effective May 1 include Emery J. Theriault, assistant chemist, and C. Harry White and Walter E. Curtis as scientific aids.

Maryland College.—Miss Katharine A. Pritchard, of Teacher's College, Columbia University, has been appointed state agent in women's demonstration work.

Michigan College.—The new veterinary building for clinical, hospital, and surgical purposes has been completed. The building is of doric design, 174 by 78 ft., and includes a wing for stabling large and small animals, operating rooms, laboratories, and offices. A special feature is the operating room for large animals, 30 by 30 ft., containing a horse operating table controlled by hydraulic power and connected with a recovery stall so that animals may be removed before recovery from anesthetics.

Minnesota University and Station.—As a result of a recent conference concerning substation work, the following general principles have been adopted: All experimental work at substations and experimental farms is to be organized on a project basis, and formulated, approved, and reported in the same manner as are central station projects. Two types of studies may be carried on at substations, (a) regional problems, organized with substation men as leaders

NOTES. 695

and with scientists from the central station as cooperators or advisors if needed, and (b) state-wide problems, organized with central station men as leaders, and with substation men as cooperators in case it is desired to use the substation as a field laboratory for a portion of the investigation.

E. W. Major has resigned as associate professor of animal nutrition, to take charge of a large dairy farm in southern California. Stephen Anthony has resigned as chemist in animal nutritition to enter the Bureau of Plant Industry of this Department. G. W. Gehrand has been appointed assistant professor of dairy husbandry, effective March 1.

Missouri University and Station.—The 1915 legislature made a total appropriation of \$108,268 for extension work. Of this sum, \$65,268 goes to offset the Smith-Lever federal appropriation, \$35,000 is for county agents, and \$8,000 is for branch short courses. Increased appropriations were also made for the two-year winter course and the soil survey, and an appropriation of \$25,000 for the erection of a new heating plant for the buildings used for teaching purposes on the farm campus. Appropriations were made for the first time for the maintenance of instruction in soils, entomology, and poultry husbandry.

Thomas J. Wornall and Charles E. Yeater were succeeded as members of the board of curators April 1 by John H. Bradley, of Kennett, and H. B. Mc-Daniel, of Springfield, whose terms will expire in 1921. F. W. Faurot has been appointed extension assistant professor of horticulture and has been succeeded as farm advisor for Buchanan County by L. V. Crandall. Other appointments include W. H. Lawrence, horticulturist at the Arizona University and Station, as professor of horticulture, Addie D. Root, of the Kansas College, as extension instructor in home economics and supervisor of girls' club work, and F. E. Longmeyer as farm advisor for Knox County. E. W. Rusk, farm advisor for Audrain County, has resigned.

Nebraska University.—H. F. Williams, of this Department, has been appointed in charge of farm management work in the State in cooperation with this Department. R. R. Stafford and E. L. Godfrey have been appointed assistants.

Nevada Station.—The recent legislature segregated the quarantine and inspection work, the director of the station no longer being chairman of the state quarantine board. The station bacteriologist has been made chief quarantine officer and all expenses of his office are to be defrayed from special state funds. An appropriation of \$2,000 was made for the use of the station farm.

The new laboratory for animal diseases has now been completed and is occupied by the departments of bacieriology and veterinary science.

New Jersey Stations.—Science states that Dr. B. H. A. Groth has resigned as plant physiologist to become director of the experiment station of the Republic of Panama, beginning April 15:

Cornell University and Station.—A plan of procedure has recently been formulated by the dean of the college of agriculture with reference to the attitude of the college to cooperative enterprises. The principal purpose sought at the present time, it is announced, will be to ascertain the facts as to the practical workings of cooperative enterprises, this study being deemed essential before the making of specific recommendations. In no case, however, is there to be participation by the institution in the administering of any cooperative enterprise or the handling in any way of its finances or business. Thus in the case of lime, it is believed that the college may advocate its use, give information as to the best formulas, the time of application, and similar points, and, under proper conditions, even suggest that farmers may combine advantageously for cooperative purchases. This stage, however, will under the pres-

ent policy end the functions of the college, and correspondence to obtain the lime or handling of the funds involved must be taken up by others.

The new soils building has now been occupied. It is a large four-story building of buff tapestry brick with white stone facings, equipped with laboratories, classrooms, lecture rooms, etc.

New courses are being offered in vegetable gardening and agricultural journalism. The former course, beginning in the spring of the Sophomore year, includes a summer of practical work with vegetable growers followed by three consecutive terms at the university, much of which is spent in outdoor laboratory work, two terms of advanced work, and graduation in September. Although attendance in the agricultural journalism course is not open to lower classmen and no credit is given, the opening lecture was attended by about 50 students and instructors.

The Farmers' Week attracted a registration of 3,877, which is believed to be the highest yet recorded in this country and an increase of about 50 per cent over 1914.

Charles S. Wilson, professor of pomology and pomologist, has been appointed State Commissioner of Agriculture. Asa C. King, a fruit grower of Trumansburg, was appointed April 1 professor of farm practice. He will engage in certain forms of extension teaching, and his work will further consist of bringing about close relationships between the college and its former students.

Oregon College and Station.—A course on extension work has been provided for the benefit of seniors who wish to specialize in the work of county agents or other forms of extension service. Lectures are to be given by specialists of the various extension sections and demonstrations made by several college and station departments.

The poultry exhibit at the Panama Pacific International Exposition has taken the form of a model poultry plant which shows yard, feeding, house and trapnest methods of poultry operations, and gives information on the results of selective breeding. An automatic picture device in the upper section of the exhibit furnishes about 50 views of famous layers and other noted fowls, gives feeding rations, and presents other points of interest in connection with poultry husbandry. Mechanical birds and attendants imitate closely the operations of the plant.

Texas Station.—New members of the board of trustees include W. C. Breihan, of Bartlett, J. F. Kubena, of Fayetteville, W. A. Miller, jr., of Amarillo, and A. B. Davidson, of Cuero. L. J. Hart, J. S. Williams, and W. A. Miller, jr., have been appointed as the station committee of the board. W. L. Boyett, supervisor of the feed control service, resigned April 15. James Sullivan has been appointed executive secretary of this service and is to be in charge of the work under the direct supervision of the director of the station.

Vermont University.—The Vermont legislature, just adjourned, made permanent the annual state appropriation of \$8,000 for extension work, which will take care of the increments for Vermont from the national funds for four years to come. It also passed a law requiring towns to assist in the financing of county agent work in counties where these agents are located.

Virginia Truck Station.—F. E. Miller, assistant horticulturist since 1912, has resigned to take up horticultural work with this Department,

Washington College and Station.—W. A. Ritz, of Walla Walla, and E. T. Coman, of Spokane, have been appointed to the board of control. C. A. Magoon has been appointed to the position of pathologist in the station. Miss Florence Ward, of the State Teachers' College of Iowa, has been appointed associate professor in rural education and assistant to the state leader in boys' and girls' club work.

NOTES, 697

The legislature at its recent session made the necessary appropriations for the duplication of the Smith-Lever fund.

National Academy of Sciences.—The Proceedings of the National Academy of Sciences are being published monthly beginning with January, 1915, by an editorial board of which Arthur A. Noyes is chairman and Edwin B. Wilson, managing editor. The Proceedings will constitute the official organ of publication of the Academy, and will contain reports of its business and scientific sessions and of its other activities. It is also intended to serve as a medium for the prompt publication of brief original papers by members of the Academy and other American investigators. Its aim will be to furnish a comprehensive survey of the more important results of the scientific research of this country, supplementing those in special scientific journals. With this end in view the papers will, in general, be much shorter and less detailed than those published in these journals. The Proceedings will aim especially to scenre promptness of publication, wide circulation of the results of American research among foreign investigators, and fuller recognition of the advances made in the separate sciences by persons more directly interested in other sciences.

The annual meeting of the Academy was held at Washington, D. C., April 19-21. Among the papers of agricultural interest were the following: Localization of the Hereditary Material in Germ Cells, by Thomas II. Morgan; Stimulation of Growth, by Jacques Loeb; Specific Chemical Aspects of Growth, by Lafayette B. Mendel; Basai Metabolism during the Period of Growth, by Eugene F. DuBois; and The Forests of Porto Rico, by Nathaniel L. Britton.

Agricultural Education in Canada.—The total student enrollment in Canadian agricultural and veterinary schools for the present academic year is reported as 1,962, the largest registrations being those of 565 at the Ontario Agricultural College and 327 at the Manitoba Agricultural College.

In Alberta, the second summer school for teachers was held at the university under the direction of the department of education, and was attended by 165 teachers as compared with 80 in the previous year. The instruction included first- and second-year work in agriculture, nature study, etc., and tirst-year work in domestic science, household arts, and physical training. A special course for the provincial inspectors of schools was given for the first time.

In British Columbia, the department of agriculture conducted 25–5-day schools for practical instruction in the pruning of tree and bush fruits, apple packing contests were held at 10 fairs, and the pupils of 24 fruit packing schools made exhibits at 18 different fairs. A boys' and girls' crop competition was also held in connection with the farmers' institutes in British Columbia for the first time, upwards of 175 entries being received. Each competitor was required to send a 20-pound exhibit from his plat to the Dominion exhibition held in Victoria and also keep a crop and financial statement. The boy and girl securing the highest total scores received respectively from the department of agriculture a pure-bred heifer calf and a high-grade sewing machine.

The department of agriculture of Manitoba is preparing to enlarge its extension work by introducing a system of tield or district specialists in agriculture located in different parts of the Province. Special instruction was given at the Manitoba Agricultural College during the winter for the purpose of fitting these men for their work. It is expected that they will not only provide technical assistance in extending approved methods of cultivation and farm management, but will also assist in improving the marketing facilities, administer the Noxious Weeds Act, and by keeping in close touch with the 14 demonstration farms already established, and others to be established, will be able to advise in regard to the approved methods of land clearing.

The number of boys' and girls' clubs organized in Manitoba has this year increased more than threefold.

A second school of agriculture in New Brunswick, to be known as the Sussex Agricultural Institute, is now being completed at an estimated cost of \$28,500.

The Summer Rural Science School for Teachers held under the supervision of the director of elementary agricultural education at Woodstock, N. B., in 1914, was attended by 68 teachers, 6 inspectors, and 1 normal school instructor. Instruction was given in nature study, horticulture, agriculture, physical nature, farm mechanics, and rural domestic science, supplemented by a series of jectures on insects, field crops, soil improvement, and practical instruction in milk testing.

Since the beginning of the organization of women's institutes in Nova Scotia in July, 1913, 11 institutes have been organized with an average membership of 25, and the tirst convention of women's institutes has been held with an artendance of 27 delegates. The 1914 legislature appropriated \$5.000 a year for the encouragement of this work.

A feature of the Nova Scotia Rural Science School, held in Truro in July, 1914, was a model school fair for which the teachers provided and arranged the exhibits. The latter included collections of grasses, weeds, and wild flowers, mounted insects, samples of chemical elements necessary to plant growth, a home canning outfit, samples of butter from the agricultural college, dairy apparatus, various fibers, samples of sugars, etc.

The total appropriations in Ontario for agricultural work carried on through the departments of agriculture and of education for the year ended October 31, 1914, amounted to \$1.311,632.75, of which \$365,658 was for the agricultural college, and \$41,200 for institutes.

 Λ new two-story and basement poultry building at the Onfario Agricultural College has been completed, and will be used for administration and instruction purposes.

To bring educational work in closer touch with agriculture, the Province of Prince Edward Island has been divided into 10 districts, in each of which an inspector has been given charge of the educational work. These inspectors will be assisted by the county representatives of the department of agriculture and by the supervisors of women's institutes. A course in nature study has been prepared for the public schools, so amplified as to be of assistance to teachers and in a general program of work for the year.

The three maple sugar making schools in Quebec, located respectively at Beauceville, Ste. Louise, and Minerve, had a total attendance of 17 students and manufactured 1,192 gal, of sirup, 555 lbs. of sugar, and 600 lbs. of sugar wax. The schools were in session 37, 18, and 9 days, respectively.

In the Province of Saskatchewan \$6.500 of the grant under the agricultural instruction act is expended by the department of education for the introduction of agricultural and domestic science courses into high schools and collegiate institutions, and the training of teachers in agriculture at the provincial normal schools. The remainder of the money is about equally divided between the college of agriculture at Saskatoon and the provincial department of agriculture at Regina. The university will spend its grant almost wholly in salaries of instructors in research, teaching, and extension, the appointments made amounting during this year to \$16,400. Instruction was given to 101 students in the regular course of the college of agriculture, to 12 men in the degree course, and to 10 registered in agriculture from other colleges of the university.

The department of education of the Province of Saskatchewan is arranging for the appointment of agricultural instructors at each of the normal schools, a part of whose duties will be the training of teachers in school gardening. NOTES, 699

Experimental and permanent plats will be established in connection with each normal school. At the Provincial Normal School, Regina, approximately 10 acres have been set aside for a model rural school garden.

Agricultural Education in the West Indies.—A school of agriculture has been started at Artemisa. Cuba, where pupils from the district schools will receive preparatory instruction in modern scientific farming. The ground, which has been donated to the school for agricultural uses, will be apportioned in small lots to individual students and seeds and fertilizers will be furnished. The department of agriculture proposes to found similar schools at different places throughout the Republic. A tract of 100 acres near Camagüey has recently been purchased.

An agricultural school for boys over 12 years of age has been established at Las Mercedes plantation, near the city of San José, Costa Rica, with the object of training practical farmers. It is under the direction of Prof. Gustavo L. Michaud, an experienced Costa Rican agronomist and educator. The instruction will be theoretical and practical, the latter including the use of agricultural machinery, elementary carpentering, blacksmithing, and brick laying.

The board of agriculture of Quezaltenango, Guatemala, has taken steps toward the establishment of an agricultural school in the vicinity of the city of Quezaltenango.

National Agricultural Institute in Colombia.—The establishment of a National Institute of Agriculture and Veterinary Science, at Bogota, with an experiment farm attached, and an auxiliary school of agriculture and animal husbandry to be located elsewhere, was authorized in December, 1914. Besides the regular 4-year course the institute will offer special normal courses in technical instruction and courses in horticulture, floriculture, arboriculture, and the cultivation and manufacture of raw materials for textiles. One scholarship will be granted by the government to each department of the Republic and 6 scholarships at large will be awarded by the minister of agriculture and commerce.

New Chinese School of Forestry.—A school of forestry has been established in the University of Nanking. Three scholarships in the school have been provided by the forestry fund committee of Shanghai, and the Philippine Bureau of Forestry has offered the services of experts in arranging the course of study, delivering lectures, and otherwise assisting in the work of organization.

New Journals.—The Annals of Applied Biology is being issued monthly as the official organ of the Association of Economic Biologists to cover the field in applied biology not now covered by special journals such as those dealing with agricultural science, parasitology, genetics, and medical science. The initial number contains the following articles: Impending Developments in Agricultural Zoology, by F. W. Gamble; The Action of Bordeaux Mixture on Plants, by B. T. P. Barker and C. T. Gimingham; Notes on the Green Spruce Aphis (Aphis abictina), by F. V. Theobald; Pollination in Orchards, by F. J. Chittenden; Life History of Pegomyia hyoseyami, by A. E. Cameron; Caterpillars Attacking Oaks in Richmond Park, by R. H. Deakin; A Bacterial Disease of Fruit Blossom, by B. T. P. Barker and O. Grove; and On the Preparation of Coccide for Microscopical Study, by E. E. Green.

The United States Public Health Service has recently begun a series of popular publications on health and hygiene. These appear at intervals as *Public Health Report Supplements*. In size and manner of presenting information they are similar to the Farmers' Bulletins of this Department, and like them they are for general free distribution in the United States and are also sold by the Superintendent of Documents at a uniform price of five cents per copy. Each number contains a concise and popular discussion by an expert of some

topic pertaining to health or hygiene, and the series should prove of special value and interest to teachers and students.

Internationale Zeitschrift für Physikalisch-Chemische Biologie is being published at Leipsie and Berlin under the editorship of Dr. J. Traube. Among the articles in the initial number may be mentioned that on the History and Development of Physico-chemical Investigations in Biology, by H. J. Hamburger: Further Studies of the Physiology of Anabolism in the Living Plant Cell, by F. Czapek, and The Catalytic Effect of Alkaloids under Various Physical and Chemical Conditions.

Annali de Chimica is being published at Rome, with G. Ampola at the head of a corps of editors and collaborators. The initial number contains an article on Rancidity in Olive Oil and the Oxidation of Oleic Acid in Sunlight, by F. Canzoneri and G. Bianchini.

An Agricultural Journal is being issued semiannually by the department of agriculture of Bihar and Orissa and edited by the staff of the Sabour Agricultural College. The initial number contains original articles, weather and crop reports, notes, reviews, notices, etc.

Die Ackerban auf Ostpreussischen Viederungsmooren is being issued by the Prussian Chamber of Agriculture with Dr. Feldt as editor. The initial number contains a report on the experimental field for moor reclamation at Bledau near Cranz.

Miscellaneous.—At a meeting of the council of the American Association for the Advancement of Science, April 20, action was taken whereby the entrance fee is to be remitted during the present calendar year to new members in Section M (Agriculture) who may join from the Society for the Promotion of Agricultural Science, the American Society of Agronomy, the Society for Horticultural Science, the American Society of Animal Production, and the Official Dairy Instructors' Association.

A scheme for teaching nature study and manual training in the elementary schools of Mauritius, together with the establishment of school gardens and workshops, has been formulated by the department of agriculture in conjunction with the director of public instruction.

The new laboratory building at the Philippine College of Agriculture for the use of the departments of physics, rural engineering, and botany has recently been completed at a cost of about \$16,500.

The Philippine legislature has appropriated \$7,500 for the establishment, equipment, and maintenance of an agricultural school in the Province of Isabela.

The Y. M. C. A. College of Springfield, Mass., has established a special department for country work under the supervision of Walter J. Campbell, formerly Pennsylvania state secretary for country work.

Science states that Dr. Fr. Ostendorf, professor of agriculture in the technical school at Karlsruhe, has been killed in the European war.

EXPERIMENT STATION RECORD.

Vol. XXXII.

JUNE, 1915.

No. 8.

Perhaps no branch of work relating to agriculture is attracting more attention at the present time than rural economics. Questions of the far-reaching influences and relations of systems and practices in farming, of cost of production, of waste and economy, of the farmer's return for his labor and investment, and many others of similar nature are seen to be of fundamental importance, and to call for special expert study. Organization and business management are looked to for the advancement of the industry in much the same way that experiment and research in production have been looked to in the past. Fortunately, provision is being made for such studies in increasing amount, and the place of this effort and its relation to the experiment station is being worked out.

A great deal of our station work has been from the very first economic in purpose and application, although it has not always been thought of as in the field of economics. It relates to a productive industry whose methods are economic, involving the elements of buying and selling, prices of supplies, cost of production, and profit and loss. And the station work has been concerned very directly with the business side of the industry, to make it more productive, more profitable, more safe as a means of livelihood. True, the station work has been thought of as largely directed at the science of production, but in fact it has very often reached over into the economics of production and distribution, especially in its simpler forms.

The subject matter of economics is defined as the study of man's efforts to get a living. The means by which he is enabled to do this through agriculture, the influences which aid and hinder him, and the proper weighing and understanding of these, are in the field of rural economics. Man's success in agriculture has resulted from his knowledge of how to control and direct the forces of nature, and this has been promoted by the accumulation and interpretation of experience, and more recently by the employment of the experimental method, which goes outside the realm of experience in acquiring facts and testing theories and traditions.

It is natural that at the outset simple, practical questions, many of them dealing with the commercial side almost exclusively, should have pressed upon the stations, and that the working out of these questions should have helped to justify the stations in the communities which they served and won for them an increasingly strong following. Such activity was warranted from its experimental character, and from the fact that the farmers usually could not perform the service for themselves. Again, the stations have found it necessary to determine for their own information and to prove to the farmers the practicability of their findings and suggestions, i. e., their business soundness or wisdom, and also to make clear the economic fallacy of certain current practices and traditions.

Whether or not we think of these activities as being in the field of economics, they border very closely upon it, and they have gone a long way toward laying a foundation for economic studies and for testing the truth of economic generalizations. As soon as we attempt to ascertain the cost of an operation or a practice or a product we are in the economic field, and the study of the factors which influence these considerations are but a step removed from it.

The range and scope of this kind of activity at the stations is very large. It has related to the cost of producing farm crops, meat, wool, and eggs, the marketing of these products, market grades, special requirements or preferences, losses in products during transit or in preparing for the market, and expense of shipment. It has likewise determined the effect of the use of fertilizers and of purchased feeds on the efficiency of production and the attendant cost of the product, and the relative profits from milk, cream, butter, and cheese. It has dealt with the cost of clearing land or otherwise reclaiming it, its relation to the returns, the cost of pumping water for irrigation and the economics of handling water, and the cost of light and power from alcohol, kerosene and gasoline in its relations to man's labor and environment. It has determined the financial returns from spraying against insects and fungus discases, the relation of age to rate of gain in live stock as an economic factor, financial returns and profits from different systems of farming, the factors which determine profits under various systems, and the effect of various forms of organization upon financial returns.

Not infrequently the experiment stations have followed the results of their experimental work even to the point of developing a new economic system. The dairy work furnishes some notable examples of this. After showing by much study the importance of the fat content of milk as measuring its value for making butter and cheese, and providing a simple method for its determination, the stations worked out the details of systems for paying for milk or adjusting dividends at creameries and cheese factories on the basis of the pounds of fat supplied by each patron, and showed its advantage and justice. The effect upon the economic status of the dairy industry has been revolutionary.

Hundreds of feeding, fertilizer, and spraying experiments have been made for the purpose of learning how to bring greater efficiency into these operations, and how to realize a reasonable profit from money and labor invested. In fact, there is scarcely a farm operation or method which has not been studied from an economic viewpoint by some of the stations. These, and the observations on their application in practice, have constituted a study of man's efforts in earning a living through agriculture.

But these activities are not all that is involved in rural economics, any more than they represent the full field of experiment station work. Although in its final analysis the ultimate object of all our station work may be economic in its application, the directness of the economic aims or bearings varies greatly, and the keeping of the economic factors too conspicuously in mind at all stages has been cited as a criticism of some of the station work. This is the case where the mere determination of the cost or the factors that enter into profit has been the ultimate aim, as for example, in the determination of the rate of gain in weight of an animal, not from the standpoint of the physiology of nutrition or the actual nutritive value or use of a feed, but primarily in relation to economic returns.

While these commercial experiments have been of great help to the farmer and have furnished a broad basis for economic studies, the objection has been made that the results represent little of permanent value, are local in application, and are sometimes little more than a demonstration of results which could practically have been anticipated. It is true that they are subject to much repetition, and are often continued beyond the actual experimental stage. Some men have seemed content to stop their work at the point where the theoretical interest begins.

The narrower range of application of these experiments may be in part due to the data not having been subjected to interpretation from an economist's point of view. The work has been carried on by agronomists, animal husbandmen, horticulturists, dairymen, and has been interpreted by them in the light of their own view and surroundings. Already there is some evidence that the attempt to make broader interpretations or generalizations from the summarized data of many experiments needs the assistance of the statistician or some one trained in the handling of data. The method of the economist differs from that of the experimenter, both in the handling of the data and the use he makes of them. There is a place for both, and some danger in attempting to combine the two functions.

It is undoubtedly true, for example, that experimental work has suffered from a confusion of economic and scientific ends. This is shown in some of our feeding trials. In the attempt to determine the effect of a certain feed upon the dairy cow the purely economic

aspects have been allowed to enter prominently into the experiment at an early stage, and sometimes well nigh to the exclusion of the study of the physiological effect. Many of our fertilizer experiments also have stopped with the immediate economic result and have failed to achieve a broader scientific value. The two ends should not be confused, or one will be likely to suffer.

In a physiological study of plant or animal it would be well if the experimenter could forget the economic side for the time being, and devote himself to determining by every means at his command the actual effect of the material or treatment upon the plant or animal, or its relation to function. The material fed to the cow may cost ten dollars a pound because it is a synthesized or artifically separated compound, and the result may be absolutely devoid of economic value. But if the study helps to a clear knowledge of the action or value of the compound as a prominent constituent of a feeding stuff, the result will ultimately be turned to economic advantage.

The recognized function of an experiment station is to acquire accurate information by means of experiment and research. For most of its workers its object is primarily the study of the theory of production and the relation of the facts developed to practical methods. It is scientific rather than speculative, and deals with facts and principles developed by investigation through science. The work of the station is on a constructive basis. While it will take account of the experience of practical men, its results will be the product of its own or similar investigations. These may be compared with results obtained by farmers, and brought into harmony with them, or used to explain deficiencies in ordinary farm practice, but they will usually be original in the sense of resting upon experimental work rather than statistics of practice.

The work of the stations is essentially experimental, dealing with conditions not only as they exist but as they are modified experimentally to determine the value of separate factors or conditions. It differs, therefore, from studies in rural economics, which deal primarily with conditions as they are found to exist and are statistical rather than experimental. The rural economist gathers data as to farm statistics, or tabulates the experience of individual farmers, or conducts economic surveys, but he also makes use of such experimental data as are available. Although he does not himself conduct experiments under modified conditions, he takes account of the results of experiments in agriculture and uses these as well as the results of general experience in developing his generalizations or theories. The experimental work of the stations may therefore be considered as contributory, and in fact it has furnished a formidable array of data for economic consideration.

editorial. 705

Definite provision for investigation and propaganda work in rural economics is gradually being made at the agricultural colleges and experiment stations. This is manifestly broader in its scope and treatment and more systematic than most of the economic work of the stations in the past. The subject is a special field in itself, with its methods and principles, and with relationships and contacts which extend into different fields from those of the student primarily concerned with the science of production.

The advantage of the rural economist is the special point of view he contributes, enabling him to trace farreaching relationships and consequences applying to the industry which would be overlooked by investigators in a narrower field of study; and beyond this he supplements the investigations of these specialists in lines not otherwise covered. For, just as the economics of agriculture includes far more than the tabulation of data of production, cost, prices, and distribution, so investigation in rural economics goes beyond the question of cost and profits as brought out in experiment, and traces tendencies and consequences of systems or conditions upon the industry and the people associated with it. It views recorded facts and the data it accumulates not merely for themselves or with reference to their direct application, but in the aggregate and in relation to their causes and their effects considered in a broad and comprehensive sense.

The complexity of modern life is as apparent in farm operations as in other fields of endeavor. Whether or not it is advisable for the Massachusetts farmer to raise wheat does not depend alone on his ability to produce good yields and to sell his wheat for more than the cost of production. It depends on a great variety of considerations relating to the economic conditions of wheat raising, competition with western and southern States, Canada, Russia, Argentina, and Australia, the probable cost of production as compared with that in competing States and countries, transportation facilities, the use of machinery and the local labor conditions, quality of the wheat as compared with wheat from other localities, adaptability of the crop to a suitable rotation system, and especially the suitability of the locality to other crops and the returns from them. A scientific study of the economics of any farm operation or system of farm management must give due consideration to these points individually, as well as to their bearing on one another and their place in a general economic system.

There is a recognized need for definite economic studies of limited range. And just here the question arises as to where such studies belong and where they can best be provided for. Some of the colleges and stations are conducting studies of systems of cropping, farm management, cost of operating farm machinery, the economy of human labor and team labor, systems of cost accounting, the efficiency of cooperative associations and other organizations, conducting agricultural surveys, etc. They are attempting to apply scientific management and the principles of economics in agriculture, not as incidental to other investigations but as a primary undertaking. This work is becoming systematized and methods for it are being developed rapidly.

As a basis for the formulation of an economic system it is often necessary to ascertain the conditions and farm practices that actually exist, the cost of production under varying farm conditions and methods, and the business aspects of various systems of farming. But such studies as an end in themselves have not commonly been considered within the special field of the experiment station. In connection with their experiments the stations have often found it necessary to take account of actual farm practice, good and bad, and to subject it to the test of experiment. But the gathering of farm data has been done as an incident to its studies and not as an end in itself.

The idea of the experiment station is opposed to the latter historically. Until the experimental method was applied, science and practice, in agriculture and elsewhere, advanced by a study of things as they were found in nature or had developed through the changes of time and also upon the basis of experience. The experiment station movement carried the idea of going outside of human experience in developing understanding and testing methods of practice, by introducing science into agriculture through the experimental method.

In this sense the station work has been thought of as experimental inquiry, rather than economic inquiry; and because the latter employed the statistical method quite largely it has been looked upon as in a somewhat different field of activity. Some forms of it, like farm management studies, have been a combination of investigation and of teaching or demonstration from the farmers' own experience. It is fully recognized that economic inquiry, like experimental inquiry, may result in new knowledge, often representing a general truth, if it does not stop at the compilation stage. And, on the other hand, it is quite possible for the stations to conduct studies which will supplement these statistical surveys, and will furnish a basis for the formulation of broader truths or generalizations.

Many of the strictly economic studies in the past have dealt with very broad questions, difficult to formulate with exactness, and difficult to support entirely on reliable data. The matter of securing the data has often been a large undertaking, and its collection has absorbed much of the economist's time. The lack of reliable and com-

EDITORIAL. 707

plete data is one of the greatest handicaps in economic studies. It has been one of the obstacles to conducting them through the experiment station.

The economist ought to have at his command sufficient data, gathered in an accurate and dependable manner. Some of these data are difficult to obtain. Their collection requires much time and the expenditure of large sums of money. Manifestly the experiment station can not be expected to furnish these data in any comprehensive way, for its appropriations, if available for that purpose, would not go far. Only in a limited way is it an experiment station function. There would seem to be need of special provision for gathering such information. This might be done by the States through their departments of agriculture or other agencies, on the advice of competent economists. The stations could often add to such statistics the results obtained by exact experimental inquiries, and in many cases such experimental inquiries are very desirable.

In the question, for example, of the cost of milk production, which is a controverted one in several States, it is not sufficient to collect data from farmers and from milk dealers and other interested parties, based on inexact records and possibly on practice which can not be fully commended. There is need of exact and reliable information, free from bias and distinguishing between what is and what should be under efficient practice. Any economic inquiry into this question of a fair farm price for milk will naturally take account of the large body of reliable information concerning the cost of producing milk which the stations have acquired; and if a station has made a careful study of the subject in all its details, in which not only the stable side but the various features connected with transportation and handling have been taken into account, its results should be of marked economic importance.

The data which serve as the foundation for rural economics vary in relative importance from year to year. Fluctuations in the labor supply, in the extent of competition, in the prevalence of pests and diseases, in the general demand for the product in question, and in the area planted to a given crop, all modify the economic status of crops and systems of farming. Loss of old markets, access to new markets and the opening and settlement of new lands also have an effect upon the market value of farm products. The establishment of new railroad or steamship lines may render a new market accessible to a given farming district, but may also open the same market to more favored competitors, thereby making unprofitable the growing of certain crops. Hence the process of gathering data must be continuous, and must be systematized so as to make the figures comparable.

To become appropriate lines of work for an experiment station, economic studies need to be clearly conceived and definitely drawn. As pointed out, the station's work is not in any primary sense the gathering of statistics or the making of surveys or the tabulation of individual experience. Economic studies, like the projects for investigation in the principles of production, require careful planning in advance, and should imply a rigid testing of the reliability of available data. They should contemplate an analysis and interpretation of the broader underlying meaning of the results, for otherwise the facts will remain isolated, disconnected facts of little dynamic force or value in a broad way. There are certain classes of statistics which are relative rather than absolute and which can be correlated with sets of conditions or systems of practice. These enable the economist to get at fairly definite and conclusive underlying principles.

There is no lack of opportunity for studies of this kind. Such questions, for example, turn on the economizing of land, labor, and capital. It has been said that in the elimination of labor waste lies greater opportunities for the constructive economist than in any other direction. A broad group of questions relating to intensive farming and its economy are suggested by the advice now being freely and widely given for more intensive cultivation, smaller farms, greater specialization, etc. How far this is sound under present conditions, and how far it is to be regarded as the solution of our agricultural problems and of cheaper foodstuffs, we must look quite largely to the economist to tell us. It would be interesting to know also how far the introduction of more scientific and rational methods might possibly modify the law of diminishing returns.

In the future work of the stations in the field of rural economics the difference must be distinguished between the formulation of economic facts and principles of agriculture on the one hand, and the active effort to put these into effective practice through the organization of farmers and otherwise. The one is investigation, the other is teaching or propaganda work. The development of effective means and plans for organization seems to occupy a middle ground. Larger attention to the economic features of farming will involve both station and extension activities, and the distinction between these will need to be clearly maintained.

The time has come when it is well for the experiment stations seriously to consider how widely the fundamental purposes and traditions of station work, taken in connection with the funds available and the need for investigation in agricultural production, will permit them to engage to any large extent in economic studies; and for each State to consider how it may best provide for gathering miscellaneous farm and other agricultural statistics which the economist will require for the formulation of the principles of rural economy.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

The total fatty acids and other ether-soluble constituents of feeding stuffs, J. B. Rather (Texas Sta. Bul. 169 (1914), pp. 5-30; abs. in Jour. Indus. and Engin. Chem., 7 (1915). No. 1, pp. 34, 35).—In some previous publications (E. S. R., 28, p. 108; 31, p. 71) "it has been shown that the unsaponifiable matter in the ether extract of hays and fodders averages about 58 per cent of the total extract, and is of much lower digestibility than the saponifiable matter. It has also been shown that chloroform extracts comparatively large percentages of material from hays and fodders previously extracted with ether, and that this extract contains fatty acids." A method was described by means of which it was possible to separate the constituents of the extract into three fractions: Unsaponified (largely wax alcohols), uncolored saponified (fatty acids), and colored saponified (chlorophyll and related compounds), and designated the digestion method.

An improved method (precipitation method) for the determination of total fatty acids and nonsaponifiable matter of the other extract has now been devised. "This method for the separation of the constituents of other extracts into three fractions is essentially as follows: Saponify the other extract, acidify and dissolve in other, precipitate the fatty acids from othereal solution with aqueous alkali, and remove by washing with water. Acidify the soap with acetic acid and shake with petroleum other to dissolve fatty acids and then with other to dissolve the residue."

Another new method is proposed which utilizes an alcoholic soda solution for dissolving the fats. "Alcoholic soda probably dissolves less nonfats than aqueous soda; soap solutions in alcohol are more easily manipulated; and fats are soluble in alcohol alone. The advantages of alcohol over water thus appear to be considerable. The use of aqueous alkali would not prevent the contamination of the soap with unsaponified material, because the latter is both soluble in soap solutions and emulsifiable with aqueous alkali.

"Ether extracts of the concentrates contained saponifiable material which does not appear to be fatty acids, averaging about 8 per cent, and unsaponifiable matter averaging about 6 per cent, a total of approximately 14 per cent of nonfats in the ether extract of concentrates. Ether extracts of hays and excrements from them contain saponified material which does not appear to be fatty acids, averaging about 15 per cent of the ether extract. Together with the unsaponifiable matter, they made a total of approximately 68 per cent of nonfats in the ether extract of roughages. Molecular weight determinations and other evidence indicate that the ether soluble, petroleum-ether soluble acids in the alcoholic soda extracts of feeding stuffs are probably fatty acids.

"The digestibility of the various ether-soluble fractions was determined in six hays with sheep. The fatty acids are digested on an average of 60.5 per cent in the ether extract; the fatty acids in the alcoholic soda extract were digested 33.7 per cent. The digestibility of the fatty acids extracted by alcoholic soda extracted by alcoho

holic soda but not by ether had an average digestibility of 14.2 per cent. The digestibility in four cases was zero. The saponified residue of the ether extract was digested, on an average, 45.1 per cent, and in the alcoholic soda extract 25.8 per cent. The nitrogen-free extract of feeding stuffs contains considerable material soluble in ether, which can be extracted by alcoholic soda. This ether-soluble matter consists of unsaponifiable matter, fatty acids, and, principally, of nonfat organic acids, in the case of hays and excrements from them. It made up from 2.72 to 12.39 per cent of the nitrogen-free extract of those samples, and averaged 5.97 per cent. In the concentrates it made up from zero to 3.84 per cent of the nitrogen-free extract, and averaged 1.49 per cent of the nitrogen-free extract."

Chemical changes during silage formation, R. E. Neidic (Iowa 8ta, Research Bul, 16 (1914), pp. 3-22; Jour, Amer. Chem. 8oc., 36 (1914), No. 11, pp. 2401-2413).—Continuing previous work (E. S. R., 29, p. 712), an examination of the contents of three types of silo, viz, wooden stave, hollow clay tile, and concrete, showed the following changes during the actual period of silage formation:

"Nonreducing sugar was rapidly changed to reducing sugar, and the latter then decreased in amount but did not disappear completely. The amount of volatile acids increased daily. In the concrete sile, as already demonstrated for the hollow tile and wooden stave siles, the racemic lactic acid produced showed a daily increase. Alcohol was formed in small amounts in each sile. Carbon diexid developed very rapidly after filling the sile. Free exygen disappeared entirely after the second or third day. The maximum temperature observed in any of the three siles was 91° F.

"Within the limits of this investigation, no differences were noted which might be attributed to differences in the material of which the silos were constructed."

Synthetic processes taking place during the autolysis of yeast, N. IWANOFF (Biochem. Ztschr., 63 (1914), No. 4-6, pp. 359-368, fig. 1; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, I. p. 911).—In this work the proteins were precipitated by enpric hydroxid, the proteoses by lead acetate, and the diamino acids by phosphotungstic acid. The nitrogen in the various fractions was estimated during the progress of autolysis. It was noted that the addition of potassium hydrogen phosphate to the mixture increased the protein fraction.

Enzyms of Aspergillus oryzæ and the application of its amyloclastic enzym to the fermentation industry, J. TAKAMINE (Jour. Indus. and Engin. Chem., 6 (1914), No. 10, pp. 824–828).—A review of the literature and some of the author's work on the use of A. oryzæ in the preparation of taka-koji. Taka-koji is suggested for use instead of malt for saccharifying cereals employed for the preparation of alcohol, etc.

Studies on enzym action.—XI, Some experiments with castor bean urease, K. G. Falk and K. Sugiura (Jour. Amer. Chem. Soc., 36 (1914), No. 10, pp. 2166–2170).—Castor bean urease (E. S. R., 30, p. 409) was found to hydrolyze much less urea than did similar soy bean preparations under comparable conditions, but the action of acids, bases, and salts on the hydrolysis of urea by castor bean urease was found to be similar to that observed by others with soy bean urease. For previous work see a note by Zemplén (E. S. R., 27, p. 633) and elsewhere.

A comparison of methods for the determination of the proteolytic activity of pancreas preparations, J. H. Long and A. W. Barron (Jour. Amer. Chem. Soc., 36 (1914), No. 10, pp. 2151-2166).—" In this paper a comparison of the

^a Hoppe-Seyler's Ztschr. Physiol. Chem., 75 (1911), No. 3, pp. 169-196.

proteolytic value of six pancreas preparations has been made by four distinct methods, the metacasein reaction, a modification of the Fuld-Gross reaction, the formaldehyde titration of amino acids liberated in digestion, and the fibrin digestion. It was hoped to find such relations as would permit the translation of activity as expressed on a given standard in terms of another.

"By the four methods the activities of the six preparations are arranged in the same general order, that is, the strongest ferment by the first method is found to be the strongest by the others. For the weakest preparations the order is about the same. But the relative rank, quantitatively, of the different ferments is very different as measured by the different methods. While the strongest ferment by the metacasein reaction appears to be about 12 times the strength of the weakest, and about 10 times as strong by the digestion of fibrin, by the other tests the relation is as 2 or 3:1. Even greater irregularities appear in comparing some of the other ferments.

"It is not possible at the present time to translate the proteolytic value of a tryptic ferment from the terms of one standard to the terms of another with the products as at present furnished by chemical or pharmacentical dealers, because these preparations are made by very different processes of extraction, concentration, or activation, which leave, probably, mixtures of ferments in widely different proportions in the finished products, and unknown amounts of inorganic salts. There is evidence to suggest that the products sold as trypsins or pancreatins contain at least two different enzyms reacting in different ways with proteins. The effects observed in any case are mixed effects depending on the proportions in which the enzyms are present. These enzyms possess different degrees of thermostability.

"The desirability of a more rational definition of trypsin is pointed out. The definition should include a statement of the essential points of manufacture and should be authorized by some responsible body, such as a pharmacopeial revision committee. Since what is called trypsin is prepared for the use of medical men, these users are entitled to the fullest knowledge concerning the composition and properties of the product. There is no excuse for secrecy here, and products should be made to conform to interchangeable standards."

Inversion of saccharose by asparaginic acid, L. Radleerger and W. Siegmund (Österr, Ungar, Ztschr, Zuckerindus, u. Landw., 43 (1914), No. 1, pp. 29-43, figs. 2; abs. in Chem. Ztg., 38 (1914), No. 35, Repert., p. 162).—Tests made with 10 gm. of sucrose and 0.1 gm. of asparaginic acid in 100 cc. of aqueous solution at 30 to 80° C, for 0 to 240 minutes resulted in showing that inversion occurs. The inverting power rises with an increase in temperature.

The preparation of raffinose, C. S. Hudson and T. S. Harding (Jour. Amer. Chem. Soc., 36 (1914), No. 10, pp. 2110–2114).—A description of a procedure by which raffinose can be prepared from various samples of commercial cotton-seed meal with a yield of 2.5 to 4 per cent. Several advantages are claimed over the method previously noted (E. S. R., 24, p. 608).

Blood pigment and chlorophyll.—Their close relation points to a common origin of animal and plant life, O. Damm (Sci. Amer. Sup., 77 (1914), No. 1999, p. 269, figs. 3).—This discusses the points which the constituents of of hemoglobin and chlorophyll possess in common in the light of new researches (Willstütter, Marchlewski, etc.).

The constituents of Clematis vitalba, F. Tutin and H. W. B. Clewer (Jour. Chem. Soc. [London], 105 (1914), No. 621, pp. 1845–1858).—A study of the climbing plant known popularly as "traveler's joy."

"The material employed consisted of the flowering branches of C. vitalba, which had been specially collected for the purpose. Preliminary tests showed

the absence of any alkaloid and that only a trace of volatile material was present. An alcoholic extract of the dried and ground material yielded, in addition to much chlorophyll and resin, the following definite compounds: (1) 3:4 dihydroxycinnamic acid; (2) caulosapogenin, $C_{42}H_{55}O_{55}$, identical with the substance recently isolated by Power and Salway from Caulophyllum thalictroides (some of the derivatives of caulosapogenin yielded on analysis apparently anomalous results, which can not at present be explained); (3) a saponin, $C_{54}H_{55}O_{55}$, which proved to be a glucosid of caulosapogenin; (4) dextrose; (5) myricyl and ceryl alcohols; (6) hentriacontane, $C_{54}H_{55}O$, and stigmasterol, which appeared to consist of a mixture of sitosterol, $C_{27}H_{45}O$, and stigmasterol, $C_{56}H_{55}O$; (8) a phytosterolin, which apparently consisted essentially of stigmasterol glucosid; (9) melissic, cerotic, and palmitic acids, together with a mixture of unsaturated acids consisting largely of linoleic acid and an acid, $C_{27}H_{45}O_{2}$ (melting point, 69.5°), apparently isomeric with behenic acid.

"The statements regarding the irritant properties of C. vitalba can not be confirmed."

Organic phosphoric acid of rice. ALICE R. Thomrson (U. 8. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 5, pp. 425-430).—In some previous work on the determination of phosphoric acid in the grain of rice (E. 8, R., 29, p. 231), it was found that when oxidizing with a mixture of hydrochloric and nitric acid a colorless solution was soon obtained, but when the solution was evaporated to dryness a charred mass remained behind. Determination of phosphoric acid in the grain (not boiled to dryness) showed only one-third of the total phosphoric acid found by the Neumann method. The foliage of the rice plant, on the other hand, showed no such differences with the two methods. "It was thought that the reason for this resistance to the action of aqua regia is probably the fact that phosphoric acid occurs in the rice grain as phytin and is therefore not completely hydrolyzed. It was decided, therefore, to give some study to the organic phosphoric acid of rice."

In attempting to obtain the pure tribarium salt of phytic acid from rice by the methods of Anderson (E. S. R., 27, p. 712; 28, p. 17; 31, p. 707), it was found that the substance was partially hydrolyzed very easily and difficulty was experienced in eliminating impurities such as other phosphoric acid esters of inosit. In the work special attention was paid to the methods for the determination of the barium and phosphoric acid in the salt. "The total phosphorus was determined in samples of rice bran and unpolished and polished rice. The following determinations were duplicated to within 0.02 per cent: Phosphorus in rice bran, 2.291 per cent; in unpolished rice, 0.321 per cent; in polished rice, 0.14 per cent."

Phytin was determined in rice bran by extraction with a 0.02 per cent hydrochloric acid solution and precipitating with alcohol. The amount found was 8.22 per cent. Attempts to obtain it in polished rice were unsuccessful.

Two preparations of barium phytate, one from rice bran and the other from unpolished rice, were made by Anderson's procedure. "The salts thus obtained were practically free from chlorids and inorganic phosphates. Nitrogen was also absent. All the material of the first preparation was used in making repeated determinations of barium, phosphorus, carbon, and hydrogen, but the phytin obtained from the bran was analyzed also for ash constituents other than barium. In 0.6 gm. of this material an unweighable trace of calcium was found, but no iron, manganese, magnesium, or potash. The residue on precipitating out the barium and igniting the phytic acid thus left amounted to a few milligrams and was composed mostly of unvolatilized phosphoric acid. No nitrogen was found in the salt." The salts contained less phosphoric acid and barium than found by Anderson for tribarium-inosit-hexaphosphoric-acid.

It could not be stated with certainty whether the barium phytate obtained was composed of a single salt of inosit,

"Inosit was prepared from the barium phytate of rice bran by heating in scaled tubes to 150° C, about 2 gm, of the salt with 20 cc, of 30 per cent sulphuric acid for five hours. The sulphuric acid was precipitated with barium hydroxid, the excess of barium removed by carbon dioxid, and the filtrate evaporated to dryness. The residue was extracted with hot water and filtered. The inosit was precipitated by other and alcohol and recrystalized three times as minute needles. These gave the Scherer reaction and melted at 223° uncorrected."

Presence of a glucosid in the sunflower, A. Zanotti (Bol. Chim. Farm., 53 (1914), pp. 4, 5; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, I. pp. 913, 914).—In the leaves of the sunflower a glucosid of the probable formula $C_{11}H_{19}O_4N_2$ was found. The substance, however, has not yet been completely purified.

The chemistry of tobacco resins, J. von Degrazia (Fachl. Mitt. Österr. Tabakregic, 13 (1913), No. 3, pp. 109–117; abs. in Chem. Ztg., 38 (1914), No. 41, Repert., p. 189).—Haid, in the sixties of the past century, noted three different constituents of tobacco resin, viz. kentuckylinic acid, C₂₂H₄₀O₅, kentuckynoleic acid, C₂₂H₂₄O₅, and kentuckynic acid, C₂₂H₄₀O₇, as well as a neutral resin, C₁₂H₂₀O₂, and an essential oil. Some of these results were verified by the author. A method for purifying the resinous constituents is given. The following were noted: α-Tobaccenic acid (probably identical with Haid's kentuckynic acid), a brittle, dark brown, odorless mass; β-tobaccenic acid, a dark green brittle mass (probably contaminated with chlorophyll); γ-tobaccenic acid, a thick, brownish fluid substance; tobacco-resinol, the resin alcohol of tobacco, which in a pure state consists of colorless needles having the composition (C₆H₁₆O₁₈; and tobacco-resene, a reddish, thick, brown fluid mass having an odor like honey and an empirical formula of C₈H₅₄O₂.

The essential oil which was found had a yellow color, a very pleasant odor, and a refractive index of 1.4882. No conclusions were drawn as to whether the essential oil is the carrier of the tobacco aroma.

The arsenates of lead, H. V. Tartar and R. H. Robinson (Jour, Amer. Chem. Soc., 36 (1914), No. 9, pp. 1843–1853).— Taken as a whole, the literature indicates that there are at least two common lead arsenates, lead hydrogen arsenate and lead orthoarsenate; that these two compounds are the main components present in ordinary commercial lead arsenate; that lead pyroarsenate may possibly be present in the commercial salts; and that there is very little accurate knowledge of the preparation and the chemical and physical properties of the pure compounds. See also a note by Holland and Reed [E. S. R., 28, p. 308]."

In this work a reliable method has been devised for the preparation of pure lead hydrogen arsenate, but all attempts to prepare pure lead orthoarsenate were unsuccessful. "Fairly pure lead hydrogen arsenate is prepared by use of the reaction between lead nitrate and disodium hydrogen arsenate."

Lead pyroarsenate was prepared and a new basic lead arsenate of apparently constant composition was obtained. "The specific gravity of lead hydrogen arsenate and basic lead arsenate have been determined. The difficulties attending the accurate determination of the solubility of the compounds prepared have been pointed out. The tests made, however, show these substances to be relatively insoluble."

According to the authors there is at the present time no method for estimating the amount of lead hydrogen arsenate in commercial arsenate of lead. It was found that "since the basic arsenate may be considered as insoluble from

the usual analytical standpoint, lead hydrogen arsenate in mixtures with the basic arsenate can be easily determined by the following described method:

"Take a convenient amount of the finely powdered sample (3 to 10 gm.), depending upon the amount of the acid salt present, which has been dried at 100°, and add 200 cc. of a 5 per cent solution of carbon dioxid-free ammonium hydroxid. Allow to digest with occasional shaking for a few hours at room temperature, when the reaction should be complete. The supernatant liquid is then filtered by suction from the insoluble basic salt by using a Buchner funnel prepared with a pad made of two sheets of filter paper with a layer of asbestos between. The upper paper should be a hardened filter. The filter is finally washed thoroughly with recently boiled distilled water until free from soluble salts. The final washings may be tested with lead nitrate solution to ascertain the completeness of the removal of the ammonium arsenate. filtrate should be perfectly clear. In case there is difficulty in obtaining a clear solution it may be overcome by refiltering through a Gooch crucible having a thin layer of carbon black on an asbestos pad. The final filtrate obtained is made up to convenient volume and an aliquot taken for the determination of arsenic. After free ammonium hydroxid is removed by boiling, the arsenic is determined by the modified Gooch and Browning method. The amount of arsenic in the total filtrate calculated as As₂O₅ and then multiplied by the factor 7,6034 gives the amount of lead hydrogen arsenate present in the original mixture.

"This method has been tried out on a number of mixtures of known composition and in each case has given good results."

"The results show that the precipitates obtained from the reactions of lead acetate and lead nitrate with disodium hydrogen arsenate under certain conditions are mixtures of lead hydrogen arsenate and the basic lead arsenate."

The estimation of sulphuric acid, sulphates, potassium, and calcium, L. Ledoux (Abs. in Bul. Soc. Chim. Belg., 28 (1914), No. 2, pp. 51, 52; Chem. Ztg., 38 (1914), No. 54, p. 575).—To 200 cc. of solution 10 cc. of concentrated hydrochloric acid and 50 cc. of a 2 per cent barium chlorid solution are added for the precipitation of the sulphates. The mixture is then shaken for one hour in the cold. Calcium is precipitated with ammonium oxalate, and the potassium is obtained as potassium platinic chlorid and reduced when warm with magnesium.

Studies upon a new method for the quantitative estimation of potassium, F. Marshall (Chem. Ztg., 38 (1914), Nos. 55, pp. 585-587; 58, pp. 615, 616).—Of the known methods for determining potassium quantitatively the platinic chlorid and perchloric acid methods are the most frequently used, although both methods, but more especially the first named, have objectionable features.

In the method proposed an aliquot of the solution containing the alkalis only as chlorids and representing about 0.05 gm, of potassium oxid is placed in a beaker and evaporated to dryness on the water bath. The residue is dissolved in as little water as possible (2 to 3 drops is usually sufficient), and an excess (20 cc.) of a 2 per cent alcoholic solution of tartaric acid (one which has stood for several days over solid potassium bitartrate and has been repeatedly shaken and then filtered) is added. After the precipitation is complete, from 10 to 20 cc. of a bitartrate-containing alcohol (96 per cent) is added and boiled for 10 minutes on the water bath. The beaker is allowed to stand covered for 24 hours, shaking, however, at intervals, and then the contents are transferred to a weighed Gooch crucible. The precipitate is washed with potassium bitartrate-alcohol and finally with pure 96 per cent alcohol, dried at 80° C., and weighed as potassium bitartrate. By dividing the weight obtained by 3.992 the corresponding amount of potassium oxid is found.

See also previous notes (E. S. R., 32, pp. 608, 609).

The microscopy of cereals and its application in the brewing industry, A. L. Winton (Amer. Brewer, 47 (1914), Nos. 5, pp. 234-236, figs. 5; 6, pp. 299-292, figs. 11; 7, pp. 341-343, figs. 9; 8, pp. 402, 403, figs. 6).—A lecture on the subject, which is illustrated with photomicrographs of the histological structure of various cereals and starches.

The examination of Belgian varieties of honey, R. Ledent (Bul, Soc, Chim. Belg., 28 (1914), No. 3, pp. 73-77; abs. in Chem. Zlg., 38 (1914), No. 54, p. 575).—The author finds that the methods of Fielie and Jaegerschmidt will detect invert sugar. The degree of adulteration can be estimated from the amount of protein, determined by Lund's method.

A new method for determining the total solids in wine, V. Njegovan (Ztschr, Analyt. Chem., 53 (1914), No. 3, pp. 160-165; abs. in Chem. Ztg., 38 (1914), No. 35, Repert., p. 157).—Five gm. of water-free sodium sulphate is weighed in a weighing bottle and 5 cc. of the wine under examination is added. After the sodium sulphate has become fully solidified the glass and its contents are placed open in a vacuum desiccator which contains about 15 cc. of sulphuric acid for each 5 cc. of wine dried, and exhausted to about 15 to 20 mm, pressure. After 12 to 14 hours dry air is allowed to enter the desiccator, and the weighing flask is then stoppered and weighed. As sodium sulphate retains a little water a control test is made without wine for the purpose of obtaining the correction necessary. The method yields good results with dry wines.

See also previous notes (E. S. R., 32, pp. 608, 609).

The specific heat of milk and milk derivatives, B. W. Hammer and A. R. Johnson (Iowa Sta. Research Bul. 14 (1913), pp. 451-463, figs. 6).—A better knowledge of the specific heat of milk and milk derivatives is deemed of the greatest importance in the conduct of various processes (pasteurizing, refrigeration, manufacturing and storing butter, and manufacturing ice cream) in the dairy industry. Two methods for determining the specific heat were evolved and these are described and the apparatus used therefor illustrated.

The samples of milk used in the tests were from the composite milk delivered at the college creamery. The fat content varied from 3.4 to 4.9, most samples having about 4.3 per cent. The whey used was from composite milk and obtained from the cheese vat, and contained from 0.25 to 0.3 per cent of fat. The creams used were separated from composite milk in the morning and kept in the refrigerator until evening when the various tests were carried out. Skim milk varying in fat content from 0.3 to 0.38 per cent was also tested. The butter fats used for the specific heat determinations were taken from the churnings on three different occasions and contained the ordinary amounts of curd, salt, water, and fat, and two other samples were carefully prepared in accordance with the specifications of the official method of analysis.

The results obtained are summarized as follows:

Specific heats of wilk and milk derivatives (including heat required to melt fat, if this factor enters).

| Kind of milk product. | At 0° C. | Λι 15° C. | At 40° C. | At 60° C. | |
|---|---|--|--|---|--|
| Whey Skim milk Whole milk 15 per cent cream 20 per cent cream 30 per cent cream 45 per cent cream 60 per cent cream Butter Butter fat | 0. 978 . 910 . 920 . 750 . 723 . 673 . 606 . 560 a . 512 a . 445 | 0.976 943 .938 .923 .940 .983 1.016 1.053 a.527 a.467 | 0. 974 952 930 899 880 852 787 721 556 | 0.972 .963 .918 .900 .836 .860 .793 .737 .580 | |

a These values were obtained by extrapolation, under the assumption that the specific heat is about the same in the solid and liquid states.

"Heretofore it has been customary to use a certain value for the specific heat of milk or cream, without paying any attention to the temperature range over which the material is to be heated or cooled. This is obviously wrong, because the range plays a very important part from the standpoint of the apparent specific heat value, and for that reason the above table was prepared, although it is recognized that certain of the values may be in error because of the assumptions that have been necessary. In addition to giving the values at certain temperatures, the table gives the values over various ranges; these were obtained by averaging the values for every 3° C.... Butter fat is composed of a number of constituents which melt at different temperatures, and the abnormal values for specific heats include the latent heats of fusion of the components of the fat." The highest specific heat found over a wide temperature range is in close agreement with the variations in the results that have been obtained for the melting point for butter fat by various investigators.

"For many practical purposes the apparent specific heat is of as great value as the true specific heat, provided the value obtained for a particular temperature interval is obtained while applying the heat at such a rate that all of the material meltable in that particular range becomes entirely melted and equilibrium is established. . . . The values near the freezing point of water are of importance in their bearing on the question of the relation of the specific heats of ice cream mixes to the effect on the palate. An ice cream very rich in fat would not only have a low specific heat at low temperature, but, as is apparent from the very great slopes of the specitic heat curves and the high maximum reached, it would adsorb heat rapidly with an increase in tempera-From the data obtained and disregarding other factors it appears that an ice cream carrying considerable fat, when first coming in contact with the warm palate and toughe, would give a sensation that was not disagreeably cold. Then as the temperature increased because of the adsorption of heat by the fusion of the fats the mass would be automatically maintained cold longer than it otherwise would remain. In short, there is no sensation of extreme coldness, but still the mass remains cold for a longer time than if smaller amounts of fat were present. On the other hand, with low fat ice creams and sherbets there is a sensation of extreme coldness when the material is first taken into the mouth, but the mass soon warms up."

The specific heat values for milk and milk derivatives collected from the dairy literature are tabulated.

A rapid method for determining crude fiber, H. Kalning (Ztschr. Gesam, Getricder., 5 (1913), No. 1, pp. 6-8; abs. in Chem. Ztg., 38 (1914), No. 11, Repert., p. 48).—The method is a modification of Weender's. It consists of diluting the mixture with water after each boiling, and, after settling, filtering the supernatant fluid through gauze. The residue in the flask is placed in a folded filter, and after the fluid has been filtered off it is retransferred to the dish and finally placed in a tared folded filter and weighed after drying. See also a previous note by Stiegler (E. S. R., 32, p. 314).

Colorimetric test for uric acid in the urine, II. F. Host (Norsk Mag. Lageridensk, Med. Selsk, Kristiania, 75 (1914), No. 7, pp. 783-791, fig. 1; abs. in Jour. Amer. Med. Assoc., 63 (1914), No. 8, p. 714).—A tabulation of the author's "findings with simultaneous application of the various color tests in vogue. They show that the Riegler method a is especially simple and reliable when the technique is slightly modified, as he describes, to render the reagent more durable. It is a 1 per thousand solution of uric acid made by dissolving 0.1 gm. uric acid in a little distilled water in a 100-cc. graduated flask; adding

10 cc. of a 0.4 per cent solution of lithium carbonate; and heating for ten or fifteen minutes until the uric acid is dissolved. Then the vessel is filled up to the mark. This solution keeps for a week. He precipitates the uric acid as animonium urate. Otherwise the technique is the same as Riegler's."

A source of error in the Clerget polarization, V. Stanék (Ztschr. Zuckeriudus, Bohmen, 38 (1914), No. 6, pp. 289-298; abs. in Chem. Ztg., 38 (1914), No. 47, Repert., p. 221).—Herzfeld's figure, 132.66, for the half-normal weight at 20° C., is noted five minutes after filling to the mark. If, however, the solution is allowed to stand for from 10 to 35 minutes the constant obtained is 0.4 per cent higher, since the rotation, as Gubbe showed in 1884, requires a certain time to arrive at a maximum, and consequently a definite time must elapse before the reading is taken. The author requests the International Commission, which is engaged in a study of the constant, to pay particular attention to this factor.

The comparative value of various germicides for use in cane sugar factories, W. L. Owen (Louisiana Stas, Bul. 153 (1915), pp. 5\{\}),....These studies were made with fresh and fermented juices, sirup, and deteriorated sugar. Formaldehyde was found to be superior to calcium hypochlorite, ammonium fluorid, sodium fluorid, milk of lime, bisulphite of lime, and bisulphite of soda for disinfecting sirup tanks or in removing the micro-organisms causing deterioration in sugars. Milk or chlorid (hypochlorite) of lime may be substituted for formaldehyde for cleaning tanks at a reduction of cost per unit of efficiency.

"In cases where the efficiency of the germicide involves any great penetrating power, as, for example, where gums are to be removed, chlorid of lime is a more economical germicide than formaldehyde. Since the efficiency of all germicides is greater at elevated temperatures, they should always be applied hot in cleaning sugar factories. The comparatively high germicidal efficiency of milk of lime, combined with its very low cost and the fact that it is always on hand in sugar factories, renders it particularly suitable as a sugar factory germicide."

A bibliography is appended.

METEOROLOGY.

Temperature records, J. B. Thompson (Guam Sta. Rpt. 1914, pp. 17, 18, figs. 2).—Maximum and minimum monthly temperatures at the Guam Station during the year ended June 30, 1914, are shown in tables and diagrams.

Ohio weather for 1913, J. W. Smith and C. A. Patton (Ohio Sta. Bul. 277 (1914), pp. 331-406, figs. 54).—The temperature and precipitation throughout the State during each month are shown in charts. The usual summary tables are given showing temperature and rainfall at Wooster and throughout the State (1888 to 1913).

The mean temperature for the year at Wooster was 50.6° F.; for the State, 52.3°. The highest temperature at the station was 96°, June 30 and August 17; for the State, 105°, June 30. The lowest temperature at the station was -2°, February 6; for the State, -15°, February 6. The annual rainfall at the station was 51.18 in.; for the State, 44.75 in. The number of rainy days at the station was 134; for the State, 120. The prevailing direction of the wind was southwest at the station and in the State at large.

Meteorological summary for the year 1913 (Wyoming Sta. Rpt. 1914, pp. 166-175).—Monthly summaries are given of observations at Laramie, Wyo., during 1913 on temperature, pressure, precipitation, humidity, sunshine, cloudiness, and wind movement. A record of soil temperature at depths of 3, 6, 12,

24, 36, and 72 in, during 1913 is also given. The growing season of 1913 was somewhat longer, the precipitation greater, and the wind velocity less than normal.

The first killing frost occurred September 17, which is later than usual. A summer frost occurred the night of July 31. The highest temperature was 89° F., July 6; the lowest, —30°, January 7. The total precipitation was 13.61 in., as compared with a 20-year average of 10.21 in. The lowest relative humidity was 15 per cent. July 2. The greatest velocity of wind was 60 miles per hour, June 41.

Salient features in the geological history of Australia, with special reference to changes of climate, W. G. WOOLNOUGH (Off. Yearbook Aust., 7 (1901–1913), pp. 56–58).—The evidences of climatic variations during the different geological ages in Australia are briefly summarized.

SOILS—FERTILIZERS.

The present status of soil chemistry, with particular reference to organic compounds, S. L. John (Landw. Vers. Stat., 85 (1914), No. 3-4, pp. 359-391).—This article is based mainly on investigations conducted by the author at the lowa and Michigan experiment stations (E. S. R., 22, p. 618; 25, p. 622; 26, pp. 320, 615, 616; 28, p. 813; 29, pp. 124, 316, 723; 30, p. 122).

The topics discussed are the sulphur compounds of the soil, the influence of meteorological and biological factors on the soil nitrogen, the older and the more recent theories regarding the nature of humus and its behavior with certain reagents, genetic relations between the chemical compounds in soil and those in plants and animals, the nature of nitrogen compounds in the soil, the organic nitrogen compounds of the soil, the separation of the nitrogen compounds in sulphuric-acid extracts of the soil, cleavage products of nucleo-proteins, lecithin products in the soil, pyridin derivatives in the soil, the ammonification of amino-acids and acid amids in the soil, the occurrence of carbon dioxid, alcohols, and aldehydes in the soil, and soil organic acids.

 Λ list of 71 references to literature bearing on the subject is appended.

On the origin of the loess of southwestern Indiana, E. W. Shaw (Science, n. ser., 41 (1915), No. 1046, pp. 104-108).—The author concludes from a study of the loess areas of the United States "that the so-called marl loess of southwestern Indiana consists of wind-deposited true loess, stream-laid valley filling, and dune sand, and that the true loess part of it, together with the 'common loess,' corresponds to the well-known loess of other parts of the Mississippi basin."

Composition and origin of different horizons of some South Russian soils and subsoils, A. I. NABOKIKH (Sclsk. Khoz. i Læsov., 237 (1911), Nov., pp. 367-379; 238 (1912), Jan., pp. 3-17; Mar., pp. 399-414; 239 (1912), May. pp. 3-14; June, pp. 159-180, fig. 1; July. pp. 289-305; abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 4, pp. 342-347).—The author deals mainly with the varying humus content of the soils as determined by the permanganate method.

A so-called isohumic zone of forest soils containing from 1 to 2 per cent of humus embraces the Governments of Kiev and Volynsk. The adjoining borderland of loess podzol clays contain not less than 2 per cent, often more than 3 per cent of humus. The soils intermediate between forests and steppes vary in humus content from that of the forest soils on the north to that of the chernozem steppes of the south. The steppes soils are divided into (1) those of the north covered with typical chernozem with 5 to 9 per cent of humus; (2) the brown soils of the coast steppes containing not more than 3 per cent of

humus, but which are frequently rich in alkali (chlorids, sulphates, and carbonates); and (3) the intermediate chestnut soils containing 3 to 5 per cent of humus.

The value of excavated subsoil (Kuhlerde) for the agricultural improvement of upland moor soils, B. Tacke (Mitt. Ver. Förd. Moorkultur Deut. Reiche, 32 (1914), No. 22, pp. 395-407).—The author briefly describes the process of excavating and mixing the deep subsoil with the surface soil of the upland moors in northwest Germany and reports crop experiments with oats, rye, and potatoes on these soils with different manurial treatments. He states that the moor soils are acid and poor in plant food, but that the subsoils are well stocked with plant food, which is made more or less available when intimately mixed with the moor soil and subjected to proper manurial treatment and cultivation. This process apparently requires several years time, however, as is shown by nine years' of cropping experiments, but in the end Important quantities of potash and phosphoric acid are made available for plants.

A simple method for determining the critical moisture content of soils, R. O. E. Davis (Jour. Indus. and Engin. Chem., 6 (1914), No. 12, pp. 1008-1010, figs. 2).—The method proposed depends upon the rise of water by capillarity a short distance in a column of dry soil and the subsequent distribution of the water in the soil.

A brass tube 1 ft, long and 1 in, in diameter is filled with the soil and suspended in water until the water has risen several inches in the tube. The tube is then removed and held in a horizontal position until capillary movement practically ceases, then moisture is determined in the inch of soil at the extreme point to which water has advanced. The percentage so found is taken to be the critical moisture content. To facilitate the operation the brass tubes are split in half, so that they can be separated and the entire soil column obtained for examination, and have a slit covered with celluloid to permit of observation of the movement of the water in the soil.

The method is considered simpler and more accurate than older methods for the purpose.

Two equipments for investigation of soil leachings, C. A. Mooers and W. H. MacIntire (*Tennessee Sta. Bul. 111 (1915*), pp. 8, pls. 4).—Two types of equipment for investigating soil leachings are described and illustrated.

The first, a pit equipment, consists of an oblong covered cement pit 81.5 ft. long, 5.3 ft. wide, and 6.5 ft. high. Thirty-four heavy galvanized iron soil drainage tanks are sunk in the ground on both sides of the pit. These are 1, 2, 4, and 6 ft. in depth, and are provided with block tin outlets which pass through the pit wall and empty the drainage water into galvanized-iron cans inside.

The second, a hillside equipment, is based upon a 6-ft, perpendicular concrete wall built against the side of a terrace in which the soil drainage tanks are sunk. The tanks are made of 14-gage galvanized ingot iron, strengthened at the top by means of a 3/16 by 3/4-in, wrought-iron band, and having a surface area of 1/20,000 acre. There are two sets of these tanks, viz. 21-12 in, deep, embedded 8 in, in the soil, and 23-24 in, deep, embedded 20 in, in the soil. Block tin tubes connected with the bottom of the tanks pass through the retaining wall and empty the drainage water into containers arranged along the wall in a covered subway. This subway is open on the side opposite the retaining wall, but is so arranged that the containers are protected from direct sunshine and other extreme weather conditions.

Ammonification and nitrification in Hawaiian soils, W. P. Kelley (*Hawaii* Sta. Bul. 37 (1915), pp. 52).—This bulletin reports studies on ammonification and nitrification in Hawaiian soils under a variety of conditions.

It was found that, as a rule, nitrification was not very active in untilled soils. Ammonification was much more active than nitrification in such soils. The inactivity of nitrification in the uncultivated soils was not due to acidity or lack of organisms, but largely to deficient aeration. Tillage improved the aeration and thus stimulated nitrification as well as ammonification. Sterilization by heat did not promote nitrification but increased the production of ammonia, Partial sterilization stimulated ammonification for a short time, usually about two weeks, after which there was a decline in ammonification. Nitrification was temporarily inhibited by partial sterilization, but later recovered its activity. Reinoculation of the partially sterilized soil with untreated soil stimulated nitrification without checking ammonification. Partial sterilization caused a permanent increase in available nitrogen (nitrates and ammonia) in certain soils and a temporary increase in others.

Calcium carbonate produced considerable stimulation of ammonification of dried blood and soy-bean meal in certain soils; in others it had little effect in this respect. Magnesium carbonate, on the other hand, produced marked stimulation in the majority of cases. Dolomitic and calcureous limestones produced much the same effects as calcium carbonate.

Calcium carbonate stimulated nitrification in certain soils and was without effect in others. Magnesium carbonate was toxic to nitrification in the majority of cases. Nitrification was as active in the manganiferous and titaniferous soils as in the others studied, but magnesium carbonate was especially toxic to nitrification in these soils, this effect being more marked in the case of soy-bean meal than in the case of dried blood. Dolomitic and calcareous limestones and calcium carbonate produced similar effects as regards nitrification.

The results regarding the effect of the lime-magnesia ratio on ammonification and nitrification were inconclusive.

In general, the experiments emphasize the importance of maintaining the best aeration possible in Hawaiian soils.

The lime-magnesia ratio.—I, The effects of calcium and magnesium carbonates on ammonification. II, The effects of calcium and magnesium carbonates on nitrification, W. P. Kelley (Centbl. Bakt. [etc.], 2. Abt., 42 (1914), Nos. 17-18, pp. 519-526; 21-22, pp. 577-582).—The experimental results contained in these two articles are reported for the most part in the above. The general conclusion is reached that the lime-magnesia ratio is not of great importance to the ammonifying and nitrifying flora of the soil. The concentration of magnesium in solution and its relations to the concentration of the other constituents are of more importance.

The influence of arsenic upon the nitrogen-fixing powers of the soil, J. E. Greaves and H. P. Anderson (Centbl. Bakt. [etc.], 2. Abt., 42 (1914), No. 10–14, pp. 244–254, fig. 1).—In continuation of previous studies on the influence of arsenic compounds on the soil flora (E. S. R., 30, pp. 423, 424) the authors found that arsenic when applied to a soil in the form of lead arsenate, sodium arsenate, arsenic trisulphid, or zinc arsenite, stimulates the nitrogen-fixing powers of the soil, this effect being greatest with lead arsenate and least with zinc arsenite. Paris green did not stimulate in any of the concentrations tested and became very toxic at a concentration of 120 parts per million. Sodium arsenate became toxic at a concentration of 40 parts per million and at 250 parts per million nitrogen fixation was entirely stopped. Lead arsenate was not toxic even at a concentration of 400 parts per million, and the toxicity of arsenic trisulphid and zinc arsenite was very small at this concentration.

"The stimulation noted . . . is not due to any inherent peculiarity of the soil used, for soils which vary greatly in physical and chemical properties had their nitrogen-fixing powers greatly increased when arsenic was applied to them.

Soils high in organic matter fixed as much nitrogen in the presence of arsenic and in the absence of mannite as they did in the presence of mannite and absence of arsenic. The stimulation is greatest when the water-soluble arsenic content of the soil is about 10 parts per million; this quantity exceeds that found in most soils, so it is likely that arsenic will stimulate in place of retard bacterial activities of soil.

"Only one type of Azotobacter was isolated which was stimulated by arsenic, and in this case the stimulation was due to the organism utilizing more economically, in the presence of arsenic, its source of carbon than it did in the absence of arsenic. Arsenic does not act as a source of energy to the organism. Part of the stimulation noted in the soil with its mixed flora is probably due to the arsenic inhibiting injurious species. A quantity of arsenic which acts as a stimulant to bacteria when placed in soil may become very toxic when tested by the Remy solution method."

Bacteriological effects of green manures, C. F. Briscoe and H. H. Harned (Mississippi Sta. Bul. 168 (1915), pp. 20, figs. 7).—This bulletin gives a general discussion of the relation of humus to soil bacteria and reports a series of experiments in stone jars which was designed primarily to test the effect of green manures and stable manure on the rate of nitrification in soils. One series of jars was arranged for the bacteriological tests and the other was cropped with oats as a check on the bacteriological tests.

The results indicated a direct relation between the bacterial count and the amount of organic matter added to the soil. There was a very uniform agreement between the bacteriological and the vegetative tests. It was found that a light dressing of stable manure with green manure produced marked effects as shown both by the crop tested and the bacterial count. The use of a bacterial culture with the green manure had as pronounced an effect as the addition of a light dressing of stable manure, indicating that the benefit from the use of the stable manure was due largely to the addition of the bacteria contained in the manure. The addition of organic matter to the soil gave not only a larger growth but a better quality of oats as shown by determinations of nitrogen in the straw.

The effect of applying stable manure with green manures, O. LEMMERMANN and A. Einecke (Mitt. Deut. Landw. Gesell., 29 (1914), No. 52, pp. 702-704).—Contrary to a generally accepted view the experiments with sugar beets reported in this article did not indicate that applying stable manure with green manures (lupines and serradella) appreciably increases the effectiveness of the latter. Plowing under the green manures in spring gave better results than plowing under about the end of October. Plowing under to a depth of 11 in. gave better results than plowing under to a depth of 8.7 in. Taking the effect of nitrogen in nitrate of soda as 100, that of the nitrogen of the green manures was 44 and of stable manure 21.

[Investigations on soils and fertilizers in Hawaii], E. V. Wilcox and W. P. Kelley (Hawaii Sta. Rpt. 1914, pp. 14-16, 21, 22, 25-27).—Brief summaries are given of the main results of investigations, including the effect of heating on soils (E. S. R., 30, p. 419), fertilizing rice (E. S. R., 30, p. 420), the nature of the nitrogenous compounds of soil (E. S. R., 31, p. 11), effect of fertilizers on the chemistry and physical properties of soils and on the fixation of fertilizing constituents by soils, and ammonification and nitrification in soils (see p. 719).

It is stated that "continued pot experiments with various forms of phosphate have demonstrated anew that soluble phosphates do not leach through the soils, but remain permanently available for plant growth. It was also shown that

legumes used as green manure greatly increased the availability of rock phosphate."

In comparative tests of various green manure plants it was found that an introduced leguminous weed known as rattlepod (Crotalaria saltiana) "has the advantage over cultivated legumes that the seed may be sown without any previous preparation of the soil and of course without cultivation after seeding.... On several plantations fields which had become the poorest on the whole plantation gave the largest yield during the past year as a result of plowing under humus-forming material, but without applying excessive amounts of commercial fertilizers."

Radio-active fertilizers (Sci. Amer. Sup., 79 (1915), No. 2038, p. 53),—Investigations by Stoklasa, noted elsewhere (E. S. R., 31, p. 821), are reviewed.

Dogfish and how it is made into fertilizer, L. H. MARTELL (Canad, Fisherman, 2 (1915), No. 1, pp. 6-8, figs. 2; Amer. Fert., 42 (1915), No. 8, pp. 54, 56, 58).—The progress made by the Canadian Government in efforts to utilize the dogfish for the manufacture of oil and fertilizer and thus reduce the menace to fisheries are discussed, and the methods used are described. It is stated that in the factories established at Causo and Clark's Harbor, Nova Scotia, and Shippegan, New Brunswick, the feasibility of so utilizing the dogfish has been demonstrated, but that the further development of the industry will probably be left to private enterprise.

The fertilizing value of feathers, F. Pilz (Wiener Landw. Zty., 64 (1914), No. 83, p. 762).—Data collected from various sources regarding the fertilizing value of feathers are summarized in this article. The analyses given indicate that feathers contain on an average about 14 per cent of nitrogen and small amounts, not more than 0.5 per cent in the aggregate, of phosphoric acid, potash, and lime. In view of the unavailable character of the nitrogen of feathers it is stated that they can best be utilized in composts.

Substitutes for ráb, J. B. Knight (Depl. Agr. Bombay Bul. 63 (1914), pp. 19).—Ráb is the term applied to the practice of burning materials like loppings of trees or dried dung upon rice seed beds before planting the seed. Tests of lime, salt, charcoal, well-rotted cow manure, sheep manure, poudrette, ashes, ammonium sulphate, superphosphate, niter, and fish and oil cakes as substitutes for ráb are reported. The results indicated that fish, niter, ammonium sulphate, and oil cakes are the most promising of the substitutes tested, but that poudrette, sheep manure, and decomposed cow manure well mixed with the soil are to be recommended.

Germany's artificial fertilizers (Ztschr. Ver. Deut. Ingen., 58 (1914), No. 40, p. 1443; Jour. Indus, and Engin. Chem., 7 (1915), No. 1, p. 74).—It is shown that Germany has a practical monopoly and an abundant supply of potash. The situation is not so favorable with reference to nitrogen, but the production of ammonium sulphate is rapidly increasing and the practicability of preparing nitrogen compounds from the air has been demonstrated, although there has not yet been any great commercial development of such processes. It is stated that Germany controls in the Haber process of synthetic production of ammonia one of the cheapest and most practical methods of producing nitrogen compounds. The phosphoric acid required is supplied by Thomas slag, a byproduct of steel manufacture, and Germany is independent with reference to this fertilizing constituent as long as the steel factories are active.

Air nitrate, K. W. Junisch (Über Luftsalpeter, Leipsic: H. A. L. Degener [1914], pp. 20, figs. 15).—The industrial development of the manufacture by electrical means of nitrates from the free nitrogen of the air by the Birkeland and Eyde and especially the Schönherr processes is reviewed and an extensive bibliography of references to literature and patents is given.

Red soils and phosphatic manures, J. Arté (Bol. Ayr. [São Pauto], 15, ser., No. 6-7 (1914), pp. 535-555, figs. 2).—The author cites analyses of 48 samples of red soils which show that these soils are generally deficient in phosphoric acid. He points out that although they rapidly absorb soluble phosphatic fertilizers, the latter usually combine with the iron and aluminum of the soils to form insoluble compounds.

He further reports experiments to show that the absorption of phosphoric acid in red soils is considerably increased by the presence of time and humus and that the solubility of the phosphates of aluminum, iron, and slag in solutions of so-called alkaline humates increases with the concentration of the solution. It is thought that the humus prevents the formation of insoluble phosphatic compounds in red soils by combining with the phosphoric acid and forming easily soluble so-called humo-phosphates. The value of liming on red soils is attributed mainly to its favorable influence on bacterial activity and on the solubility of potash.

It is concluded that superphosphate may be profitably used on red soils if accompanied by liberal additions of organic matter and lime.

The white phosphates of Tennessee, J. S. Hook (Resources Tenn., 5 (1915), No. 1, pp. 23–33, figs. 4).—The character, geological relations, origin, and distribution of the white phosphate deposits occurring in Perry and Decatur counties, Tennessee, are discussed. Sufficient investigation has not yet been made to determine definitely the extent of these deposits. The deposits are so irregular and uncertain in character that no reliable postulations can be made as to the extent and size of the individual deposits.

Phosphatic fertilizers and the deposits of apatite of Freirina, J. Brüggen (Los Abonos Fosfatados i los Yacimientos de Apatita de Freirina. Santiago de Chile: Soc. Nac. Min., 1914, pp. 12, pl. 1).—This article discusses briefly the sources, character, and fertilizing value of various phosphatic fertilizers, and describes in some detail what appear to be large deposits of high-grade apatite occurring in the Department of Freirina, Chile. A considerable part of this apatite contains from 25 to 29 per cent of phosphoric acid and some of it as much as 35 per cent.

American imports of potash salts (U. S. Dept. Com., Com. Rpts., No. 17 (1915), p. 293).—The import into the United States during December, 1914, of muriate of potash was 8.313 tons, sulphate of potash 2.204 tons, other salts 503,349 tons, as compared with 28.619, 6.459, and 695,373 tons, respectively, during December of the preceding year.

The economic value of Pacific coast kelps, J. S. Burd (California Sta. Bul. 248 (1915), pp. 183-215, figs. 3).—This bulletin reports in part the results of an extensive series of studies on the chemistry of kelps, discussing these results from the standpoint of their bearing on the commercial utilization of kelp.

The following are the general conclusions reached: "The giant kelps contain potassium, iodin, and nitrogen in amounts which will possibly justify commercial recovery. Estimates of potash yields which are based on analyses of leaves and stems and do not take into account the larger proportion of leaf to stem in the growing plant are likely to be higher than can be expected in the average run of commercial recovery. Exact determinations of the moisture content of the more common of the giant kelps, here presented for the first time, show that weight for weight of fresh kelp Macrocystis pyrifera contains more of each important constituent than does Nercocystis luctkeana.

"The efflorescence of potash salts when kelps are slowly dried can not be utilized to advantage in the commercial preparation of potash if a large yield of high-grade salts is desired. No technological difficulties are involved in preparameters.

ing high-grade potash salts and iodin from kelp, but exact costs of production can only be arrived at from data obtained on a large scale, as in actual factory practice. Apparently, however, extraordinary profits are not to be expected owing to the limited value of the product and the large amount of manipulation involved in the various methods of recovery.

"Alr-dried kelp will furnish a low-grade potash fertilizer comparable to kainit and containing in addition over 1 per cent of nitrogen and 50 per cent of organic matter capable of furnishing humus to the soil. Objections to the use of dried kelp because of the presence of sodium and chlorin are untenable, because this material contains less sodium and chlorin than most of the commercial potash salts now being used and is but little inferior in this respect to the highest grades of muriate."

The relation of sulphur to soil fertility, O. M. Shedd (Kentucky Sta. Bul. 188 (1914), pp. 595-630).—Determinations of sulphur in a large number of vegetables and fruits and other materials are reported showing widely varying but, in certain cases, considerable amounts of this constituent. For example, of 31 varieties of tobacco grown in Kentucky only two contained less sulphur than phosphorus. The larger proportion contained considerably more sulphur than phosphorus; in some cases twice as much. The average sulphur content of all the varieties examined was 0.458 per cent, the phosphorus content 0.302.

The addition of sulphur (100 and 500 lbs, per acre) or gypsum (equivalent to 100 lbs, of sulphur per acre) to fertilizers containing only nitrogen, potassium, and phosphorus produced a decided increase in yield in pot experiments with tobacco on a soil containing 240 lbs, of sulphur and 860 lbs, of phosphorus per acre. There were decided gains in the growth of soy beans with applications of sulphur, ammonium sulphate, pyrite, and ferrous sulphate and smaller gains with calcium, potassium, barium, magnesium, aluminum, and sodium sulphates on a soil containing 600 lbs, of sulphur and 3,040 lbs, of phosphorus per acre. The best results were obtained with the element sulphur. Pyrite and ferrous sulphate were applied at rates furnishing 6 lbs, of sulphur per acre; the other materials in amounts supplying 100 lbs, of sulphur per acre. The sulphur content of soy beans which responded to sulphur fertilization was in all cases higher than that of beans which had not been fertilized with sulphur. The sulphur fertilizers were also found to increase materially the growth of turnips following soy beans on the same soil.

Clover was not benefited by sulphur fertilizers on soil from the same source as that used in the experiments with soy beans. In a series of experiments with cabbage on soil, from the same source, to which were added in small amounts ferrous sulphid, disulphid, and sulphate and ferric sulphate and oxid, sulphates and carbonates of nickel, copper, cobalt, chromium, manganese, and lithium; ammonium, potassium, and sodium sulphocyanid; and flowers of sulphur none of the sulphur compounds except potassium sulphocyanid proved beneficial. few of the substances used had no effect, while several were harmful. In similar experiments with mustard following the cabbage good gains in yield were obtained with several of the sulphates. With radishes following mustard the results were more irregular, but indicated benefit from sulphur fertilization in some cases. Experiments with alfalfa in sand cultures showed that this plant readily utilizes different forms of sulphur. The best results were obtained with magnesium, ferric sodium, potassium, and ammonium sulphates. Good results were also obtained with elementary sulphur. In nine out of fifteen cases the sulphates gave better results than the carbonates of the same element.

It was found that when sulphur was added to the soil it was rapidly oxidized to the sulphate (60 to 80 per cent in four months), the oxidation proceeding more rapidly in a fertile soil than in a poor soil. Sulphur was also oxidized

in sand cultures, but not to the same extent as in soil. The oxidation of the sulphur resulted in an increase of acidity. The organic sulphur of horse manure was slowly oxidized to sulphate.

The work of other investigators on the subject is briefly reviewed and a bibliography of the subject is given.

The action of salts of manganese on the growth of plants, P. Andouard (Bul. 8ta, Agron. Loire-Inf., 1912-13, pp. 125-141).—Field experiments testing the effect of manganese carbonate (89 lbs, per acre) and sulphate (35.6 lbs, per acre) on the growth of beets, beans, and potatoes are reported, the results showing that the yield was in every case increased by the application of manganese salts. The increase was generally more marked with the carbonate than with the sulphate. The effect on the different constituents of the plants varied with the salt used.

[Inspection of fertilizers in Alabama], B. B. Ross (Ata. Dept. Agr. Bul. 64 (1914), pp. 133).—Analyses and valuations of fertilizers collected during the inspection of 1913–14 are reported with brief discussions on the maintenance of soil fertility, classification of fertilizing materials, and home mixing of fertilizers. The text of the state fertilizer laws are included.

[Inspection of fertilizers in Florida], R. E. Rose and F. T. Wilson (Ann. Rpt. State Chem. Fla., 1914, pp. 54-106).—Analyses of fertilizers collected during the inspection of 1914 are reported.

Inspection and analysis of commercial fertilizers, 1914, F. B. MUMFORD and P. F. TROWBRIDGE (*Missouri Sta. Bul. 122 (1915*), pp. 109–160, fig. 1).—A list of fertilizers registered for sale in Missouri in 1914 is given and analyses and valuations of about 500 samples of these are reported with comments. There was a marked increase in the use of fertilizers in the State in 1914 over 1913. The deficiencies in nitrogen, phosphoric acid, and potash found by analysis, as compared with the guaranties, were greater in 1914 than in 1913, and in all constituents except potash greater than for the preceding five years. In 1914, 49.4 per cent of the nitrogen determinations, 28.2 per cent of the phosphoric acid determinations, and 27.6 per cent of the potash determinations were below the manufacturers' guaranties. However, the average value of all fertilizers examined in 1914, as calculated on the basis of their composition, was 57 cts. per ton above the average guaranty.

AGRICULTURAL BOTANY.

The evolution of sex in plants, J. M. Coulter (Chicago: University Chicago Press, 1914, pp.~IX+140,~figs.~46).—This is the first of a series of publications issued by the University of Chicago, in which it is intended to present summaries of experiments or specific investigations. The treatment of the topics is to be as nontechnical as possible, the series being intended for the layman as well as for the scientist.

In the present volume the author discusses asexual reproduction, the origin and differentiation of sex, evolution of sex organs, alternation of generations, differentiation of sexual individuals, and parthenogenesis. A working hypothesis is suggested regarding the theory of sex, and he concludes that sexuality as a method of reproduction represents protoplasts engaged in reproduction under peculiar difficulties that do not obtain in reproduction by spores or by vegetative multiplication. Its significance lies in the fact that it makes organic evolution more rapid and far more varied.

The mode of inheritance of semisterility in the offspring of certain hybrid plants, J. Belling (Ztschr. Induktive Abstam. u. Vererbungslehre, 12 (1914), No. 5, pp. 303-342, figs. 17).—This is a study of semisterility as related to

abortion of young pollen grains and embryo sacs in three species and one variety of Stizolobium,

After discussing the particular and general effects of crossing in each of three generations, the author states that six families of the fertile plants have been grown on a large scale in the fourth and fifth generations, and all proved fertile, three of the lines obtained being of agricultural value. He presents a working hypothesis claimed to account for all facts at present known in this connection.

Plant chimeras, P. Popenoe (Jour. Heredity, 5 (1914), No. 12, pp. 521-532, figs. 9).—This is a discussion of so-called graft hybrids, including mention of early cases observed and later cases studied, recent experimental production of these chimeras with explanations of their behavior as regards chlorophyll characters and chromosome numbers, and mention of what is possibly the only genuine graft hybrid (Solanum darwinianum) now known.

Heredity in chimeras, W. S. Chapin (Jour. Heredity, 5 (1914), No. 12, pp. 533-546, figs. 7).—This is an account of the study of the progeny of a specimen of Amaranthus retroflexus which possessed variegated leaves and was regarded as a sectorial chimera. The offspring consisted of green, white, and a few variegated seedlings. Only green offspring were produced from green seedlings or green branches, and white branches when self-fertilized (cross-fertilization not being tried) produced only white offspring. It is thought that the heredity of this plant belongs to the type of variegated chimeras, the variegated plants coming from a cross between green and white gametes.

Bud variations in Coleus, A. B. Stout (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 178).—The author states that plants propagated vegetatively through six generations develop two types of changes, fluctuations and mutations. Although the different patterns which arose were remarkably constant in vegetative propagation, each exhibited further changes in the epigenetic development and distribution of the red pigmentation. The phenomena associated with the appearance and subsequent behavior of the different bud variations are quite similar to the phenomena of variation, mutation, and alternative inheritance in a seed progeny of hybrid origin.

Inheritance of certain seed characters in corn, R. A. Harper (Abs. in Science, n. ser., 41 (1915). No. 1048, pp. 177, 178).—The author states that the various pigmentations of the integrment, aleurone layer, and endosperm are metidentical characters, that is, the same in the cells as they are in the tissues or kernel as a whole. The pattern in the case of streaked or mottled grains is a character of the tissue as a whole. The form of the dent kernels is a character of the kernel due to the nature and distribution of the starch and other elements in the tissues. The wrinkled form of the kernels of sweet corn is more nearly identical with the shrinkage of the individual cells of the endosperm. By crossing these different forms intermediates may be obtained between any two contrasting characters, and selection tends to develop fixity of type, although the range of variation may at first be even higher than that of either parent.

Inheritable variations in the yellow daisy, A. F. BLAKESLEE (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 178).—From a study of the yellow daisy (Rudbeckia hirta) the author has found a large number of ray characters, such as absence, reduplication, length, color, constriction, transformation of rays into tubes, and differences in shape, size, and color of disk, as well as vegetative characters, such as height, branching, leaf character, fasciations, etc.

Enothera lamarckiana and the Enotheras of the forest of Fontainebleau, L. Blaringhem (Rev. Gén. Bot., 25 bis (1914). pp. 35-50. fig. 1).—The author

concludes an account of studies carried out on Œnothera by stating that there may be found in a wild state in France at least four distinct species of the group Euœnothera, namely (in order of frequency of occurrence) $(E.\ biennis,$ $(E.\ biennis,\ parviflora,\ and\ (E.\ muricata,\ (E.\ longiflora,\ not belonging to that group. <math>(E.\ lamarckiana)$ is probably not found growing spontaneously in France.

A study of the genus Panicum, S. A. Belov ($Trudy \ B\widehat{u}vo \ Prikl. \ Bot.$ ($But. \ Angew. \ Bot.$), 7 (1914), No. 5, pp. 306–324, figs. 27).—Studies in water requirement as related to development at the agricultural station of Samara are said to show that $P. \ miliaceum$ starts its main growth after wheat has passed its maximum, the principal root development of this millet corresponding with the latter part of stalk growth and with the early period of panicle formation.

Several other species of Panicum studied are said to fall naturally into three groups, in one of which there is considerable development of conducting tissue as compared with a given stomatal area, in a second, like development of conducting tissue with smaller stomatal area, and in the third, correspondence of stomatal area with development of conducting tissue.

Coloration of glumes in Panicum miliaceum, B. Arnold (Trudy Bûro Prikl. Bot. (Bul. Angew. Bot.), 7 (1914), No. 5, pp. 293–305, pl. 1, fig. 1).—This is an account of a series of comparisons made by the section for plant breeding at the Saratov Experiment Station regarding coloration of glumes in 265 pure strains within 23 varieties of millet, which were carried out with colors employed there as standards.

It was found that each variety of so-called red, yellow, and gray millet has a prevailing color tone, others showing lower degrees of conformity to type.

The relationships of root bacteria in the Leguminosæ, J. Simon (Centbl. Bakt. [etc.], 2. Abt., 41 (1914), No. 11-17, pp. 470-479).—A study of the relationships of nodule bacteria through their interaction with the leguminous hosts is said to divide the bacteria into groups, each form reacting with a certain number of hosts, which are indicated. The root bacteria of the Leguminosæ, it is held, are to be considered as more or less constant adapted forms of the species Bacterium radicicola.

Isolation of Bacillus radicicola from soil, C. B. LIPMAN and L. W. Fowler (Science, n. ser., 41 (1915), No. 1050, pp. 256-259).—A method is described by which the authors claim to have isolated B. radicicola from soil in which there had grown for several years a large specimen of Vicia sicula. The organism was isolated, and inoculation experiments showed that in 21 out of 44 instances bacteria isolated from soil gave positive results, as shown by the presence of nodules on the roots of plants as grown in cultures. This is believed to be the first recorded instance where B. radicicola has been isolated directly from the soil.

Physiological studies of Bacillus radicicola of soy bean, J. K. Wilson (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 180).—This investigation is said to confirm other earlier work regarding the influence of nitrates on nodule production, and indicates that sulphates in relatively weak concentration inhibit the process. Chlorids and phosphates stimulate nodule production, while ammonium salts are inhibitory. It was determined that while nodule development was prevented by the presence of nitrates, sulphates, and ammonium salts, yet the organism retained its vitality in the presence of these salts. Whether the effect of the salt is upon the root, such as to make it more resistant, or upon the organism has not been determined.

Influence of certain salts on nodule production in vetch, Kno (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 180).—The author claims that calcium salts are essential for nodule production in vetch, although the substitution of

burium or strontium permits nodule development to a limited degree. The relation of a balanced solution to nodule production has also been investigated.

The assimilation of elementary nitrogen by yeasts and mold fungi, A. Kossowicz (Biechem, Ztschr., 64 (1914), No. 1-3, pp. 82-85).—The author has followed up investigations previously reported (E. S. R., 28, p. 35; 31, p. 223), and claims that the yeasts and mold fungi tested are able to utilize nitrogen compounds existing in the air, but not the free nitrogen thereof. He considers it doubtful whether yeasts or mold fungi exist which can utilize such atmospheric nitrogen.

Distribution of nitrates in Phytolacca, R. Spallino (Ann. Chim. Appl. [Rome], I (1914), No. 11-12, pp. 502-505, pl. 1).—A preliminary study of the nitrate content in growing portions of Phytolacca at different stages is considered to show that nitrates in this plant have the character of reserve material, a relation being noted between the degree of leaf activity at a given stage and nitrate distribution in the plant.

The rôle of calcium in forest vegetation, L. Chancerel (Rev. Gén. Bot., 25 bis (1914), pp. 83-89, pl. 1).—Giving a brief account of tests of the influence of several compounds upon the development of a number of common forest trees, the author states that calcium salts exercise an accelerating influence (not completely nutrient, but probably strongly stimulant) on a number of forest growths, producing notable results without injury in some instances. The maritime pine was found to accommodate itself to a high proportion of calcium and to show much greater vigor than in a siliceous medium. Chestnut was cultivated in a saturated solution of either sulphate or carbonate of calcium, which exercised a favorable influence on this plant. In general, while other conditions are influential, calcium compounds, particularly as sulphate or as phosphate, exercise a most important influence in silviculture.

Growth of plants in a medium rich in carbon dioxid, W. Berkowski (Gartenwelt, 17 (1913), No. 51, pp. 707-709, figs. 2; 18 (1914), No. 33, pp. 445, 446, figs. 3).—Reporting experiments on several plants, the author states that increase of carbon dioxid in the atmosphere did not improve the appearance, flowering, or body weight of the plants tested.

On the nature of antagonism, W. J. V. OSTERHOUT (Science, n. ser., 41 (1915), No. 1050, pp. 255, 256).—The author presents a hypothesis formulated as a result of his investigations on the permeability of protoplasm, by which one may predict what substances will antagonize each other and what degree of antagonism will exist between any two substances. Substances which alter the permeability of protoplasm, it is said, may be divided into two classes. (1) those which cause an increase, but not a decrease, of permeability, and (2) those which can produce a decrease of permeability.

As a result of his investigations the author claims his hypothesis offers a rational explanation of antagonism by showing that salts antagonize each other because they produce opposite effects on the protoplasm and indicates definitely what the effects are. From this it is possible to predict, both qualitatively and to a considerable extent quantitatively, the effect of combinations of salts, but this may also be extended to organic compounds and to show that nonelectrolytes which decrease permeability can also antagonize such substances as sodium chlorid. This indicates that the hypothesis may be applied so as to include both electrolytes and nonelectrolytes.

Senile changes in the leaves of Vitis vulpina and certain other perennial plants, H. M. Benedict (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 180).—Through investigations extending over a period of seven years, the author has found that leaves of V. vulpina and other plants exhibit evidence of senility. Leaves of old plants have a higher percentage of vascular tissue than leaves of

young plants, and consequently they are less efficient as photosynthesizing organs. He obtained a formula showing means for determining the age of V, vulpina from its veinage, as the age (age being reckoned from the last reproduction from seed) of a plant of V, vulpina determines the character of its veinage. The juvenile veinage is restored only after sexual reproduction.

The effects of kerosene and other petroleum oils on the viability and growth of Zea mays, J. H. Whitten (Bul. Ill. State Lab. Nat. Hist., 10 (1914), Art. 5, pp. 245-273, pl. t. fig. 1).—The author reports on several series of studies with Zea mays as affected by kerosene under different conditions.

Grains of corn were not injured by immersion in kerosene for from 10 to 20 days if they were then freed from adhering oil and given very little moisture during germination and initial growth. Dry, uninjured membranes were impermeable to kerosene, but moist membranes were not.

While some uninjured grains of corn may remain in kerosene for eight years without detriment, mechanical injury to the membranes permits destruction of life in the embryo by kerosene within 75 days.

Kerosene, while harmless in small proportions, was above these injurious to germinating grains in proportion to length of time of immersion and increase in water content of the soil above the minimum required for germination. Older seedlings absorbed safely larger quantities of kerosene. The injurious effects of petroleum oil on germinating seed corn seemed to vary inversely as the volatility of the respective oils.

It is not considered advisable to treat seed corn with kerosene unless the water content of the soil is under control.

Injuries to plants by smoke, gas, and ashes, H. C. MÜLLER ET AL. (Ber. Agr. Chem. Kontroll u. Vers. Stat. Pflanzenkrank. Prov. Sachsen, 1913, pp. 21–23).— This is a brief report on the chemical or physical injuries to various classes of useful or ornamental plants by gaseous and solid emanations from locomotives, electric plants, and other sources of abundant combustion products. The injuries due to nematodes, etc., attacking the plants weakened by the action of such products are included.

FIELD CROPS.

Report of the agronomy department, C. K. McClelland and C. A. Sahr (Hawaii Sta. Rpt. 1914, pp. 36-42, pl. 1).—In a test with rice, a Japanese variety, Bezembo, and a Chinese variety, Long Nyah Yin, are noted.

"In an experiment with a sweet sorghum, a nonsaccharin sorghum, and Japanese cane for yields of forage over a long period, the sweet sorghum has yielded in four cuttings 47.1 tons per acre and the nonsaccharin variety 49.8 tons in three cuttings. The Japanese cane, cut for the first time, yielded 102 tons of forage per acre 453 days after planting."

Sudan grass planted November 22, 1913, is noted as yielding 31 tons of green forage at the first cutting, March 9, 1914, and 30 tons at the second cutting, May 8. Sudan grass seems to be much superior for lower and Tunis grass for higher elevations. Among other grasses "Mitchell grass (Astrebla triticoides), Judd grass (Leptochloa virgata), Paspalum stoloniferum, molasses grass (Melinis minutiflora), P. virgatum, Phalaris bulbosa, and Texas blue grass are worthy of mention. The American 'Buffalo grass' (Bulbilis dactyloides) from Kansas seed started very slowly but is making much better growth as the summer months come on."

Three varieties of saltbushes are mentioned as having shown desirable qualities as sturdy, long-period cover crops, namely, *Atriplex nummularia*, *A. leptocarpa*, and *A. halimoides*. Trials with buckwheat, flax, and rape show these to be crops of value for Hawaiian conditions.

The trials of legimes include Lupinus hartwegii, which yielded at the end of 84 and 96 days, respectively, 9.8 and 18.6 tons green manure and 16.5 bu, seed per acre, Trifotium atexandrinum, Desmodium tortuosum, Sanguisorba minor, Cytisus proliferus, Onobrychis satira, and Lotus corniculatus.

Agronomical investigations, E. V. Wilcox (Harraii Sta. Rpt. 1914), pp. 17, 18, 19, 20).—This outlines the general scope of the agronomical work of the station, discussing the rice experiments, the unsatisfactory growth of cereals, the favorable prospects for Sudan grass, Giant Berminda grass, teff grass, and saltbushes as forage plants, an unsatisfactory attempt to grow potatoes on account of blight, the excellent results with buckwheat and tlax as farm crops, the increasing use of algaroba meal, and the increasing use of dynamite in improving soil conditions. The great value of the use of arsenite of soda as a spray to destroy weeds is also noted. The effect of arsenic on the soil is being studied.

Report of the eastern Oregon dry farming branch experiment station, Moro, Oregon, 1913–14, D. E. Stephens (Oregon Sta., Rpt. East. Oreg. Dry Farming Sta., Horo, 1913–14, pp. 42, figs. 14).—This bulletin embraces brief notes on the establishment of the eastern Oregon dry-farming substation at Moro, its equipment, and the climatic and soil conditions found there, including meteorological data.

Results of experiments that have been carried out along the lines of variety tests, tillage experiments, and crop rotations are given in detail and summarized as follows: "Improved strains of the Turkey winter wheat, in a 4-year period, have averaged 8 bu, an acre more than the local Fortyfold. For a 3-year period the Kharkov winter wheat has exceeded the best local Turkey wheat by 4.6 bu, an acre. Early Baart spring wheat and selections from Koola, Karun, and C. I. No. 2495 have given yields from 4 to 5 bu, an acre higher than the Selected Bluestem, the best local spring wheat. . . .

"The average yield of 63,000 acres of spring and winter barley in the Columbia Basin counties of Oregon in 1909, according to the U. S. Census, was 15.5 bm, an acre. The 4-year average yields of the Mariout, Hannchen, and Swanneck spring barleys on the branch station farm have been 26 to 29 bm, an acre.

... For a 4-year average the leading out varieties have been Kherson, Canadian, Siberian, and Sixty Day. A selection of the Sixty Day in 1914 out-yielded the best local out variety by 20 bm, an acre. Tests with winter and spring enumer indicate that this crop will not likely supplant outs and barley for stock feed in eastern Oregon. That field peas can be grown with profit on eastern Oregon dry lands has been demonstrated. The Carleton variety on the same ground in 1912, 1913, and 1914 averaged 19.3 bm, an acre, at present prices worth about \$35. . . .

"The best corn varieties for eastern Oregon conditions have been found to be Walla Walla White Dent, Northwestern Deut, Minnesota No. 13, Windus White Dent, and Yellow Flint. Corn varieties grown for a number of years and selected at the branch station have always given higher yields an acre than corn grown from seed of the same varieties obtained from distant localities.

"Alfalfa in cultivated rows has given promising results on the dry upland soils. The Baltic and Grimm varieties are recommended as best suited to eastern Oregon conditions.

"The permanency of the agriculture of eastern Oregon will depend upon the adoption by the farmers at some time of a crop rotation scheme that will increase and maintain the fertility of soil that is being depleted by continuous grain growing. Eighteen different crop rotation schemes are being tried at the

branch station; and, though further trials are needed before it can be decided which systems will be most profitable for farmers to adopt, results already obtained indicate that such crops as field peas, corn, and alfalfa in cultivated rows can, in a large measure, be substituted for summer fallow. In an extensive test of different cultivation methods for winter wheat under the summer fallow system it has been found that from 4 to 10 bu, an acre is gained by plowing the ground earlier in the spring than is the common practice."

Variety testing (Washington Sta. Bul. 118 (1914), pp. 18-22, fig. 1).—Data are given regarding variety tests of winter and spring wheat, winter and spring barley, oats, and field peas.

Grasses and forage plants of Hawaii, C. K. McClelland (Hawaii Sta, Bul. 36 (1915), pp. 43, pls. 9).—This bulletin gives a detailed idea of the present status of forage plants on the various Hawaiian ranches. Tables show the average annual and monthly precipitation at some Hawaiian ranches and other points for periods ranging from 5 to 27 years; analyses and compiled data as to the composition of Hawaiian feeds; the Hawaiian, common, and botanical names of the more important grasses and leguminous and miscellaneous forage plants; the names of grasses introduced for range improvement but not yet established; and undesirable and poisonous plants. Descriptions of many of the forage plants are given and recommendations for planting are offered, together with brief notes on the management of range lands.

Forage crop studies, J. B. Thompson (Guam Sta, Rpt, 1914, pp. 15, 16, pl. 1).—This notes the production of Para grass, Paspalum dilatatum, Guinea grass, sorghum, and peanuts for soiling and pasture crops.

Brachysm, a hereditary deformity of cotton and other plants, O. F. Cook (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 5, pp. 387-399, pls. 10).—In this article the author discusses facts discovered by observations of the cotton plants under the headings of special features of brachysm in cotton, independent origins of brachytic variations, different degrees of brachysm, shortening of internodes by drought, retention of blasted buds in brachytic varieties, morpholgy of decurrent pedicels, brachysm accompanied by fasciation and adhesion, analogy between brachytic variations and hybrids, brachysm and homoeosis, and agricultural defects of "cluster" cottons.

In conclusion it is stated that "brachysm is a term proposed to designate the shortening of the vegetative internodes of plants. It is a hereditary abnormality, indicating degeneracy, that has appeared in independent mutative variations in many distinct families of plants, including many cultivated forms. Brachytic variations are of frequent occurrence in cotton, giving rise to the so-called 'cluster' and 'limbless' varieties, and afford unusually favorable opportunities for learning the nature and physiological significance of such variations.

"The shortening of the internodes of the cotton plant is usually confined to the fruiting branches without affecting the main stalk or the vegetative branches. Brachytic variations occur independently in different species and varieties of cotton and do not constitute a natural group with a common origin.

"Brachytic varieties of cotton usually show other abnormalities of the internodes, leaves, and involucral bracts. There is also an increased tendency to abortion of the floral buds, and the blasted buds often remain attached to the plant, because of the absence of well-differentiated absciss layer at the base of the pedicel.

"Though brachytic variations arise by mutative changes in the expression of the characters and show alternative Mendelian forms of inheritance, they afford no additional support to the general theories of mutation and Mendelism as explaining evolution. Such variations represent reduced specialization or

intermediate expression of characters and are degenerative in nature. They are not to be considered as examples of normal heredity or of the evolution of new characters. The abnormalities of brachytic variations are analogous to those found among hybrids and are likewise accompanied by tendencies to sterility or abortion of buds.

"Brachysm is to be associated with other forms of intermediate expression of characters, representing a general class of metaphanic variations. A more definite recognition of this class of variations is desirable in connection with the investigation of general problems of heredity and evolution.

"The agreultural value of brachytic varieties of cotton is impaired by the tendency to abnormal variations and sterility and also by the fact that the cluster cottons are more severely affected by unfavorable conditions. Hence, brachysm is to be avoided in the breeding of superior varieties of cotton."

Crimson clover: Seed production, J. M. Westgate (U. S. Dept. Agr., Farmers' Bul. 646 (1915), pp. 13, figs. 13).—This describes methods of harvesting the seed of crimson clover and also describes devices for gathering the seeds, known as comb strippers and rotary brush strippers.

Brief notes are given on the commercial growing of crimson clover seed and how to grow a good crop of seed, and the money values of a seed and hay crop are compared. The weeds to be avoided in a crimson clover field are mentioned and illustrated. Because of the uncertainties of the foreign supply of seed, it is suggested the individual farmer may readily arrange to save his own seed for reseeding, although the commercial production of seed in this country is handicapped by frequent untimely rains.

Local fertilizer experiments with corn in south Alabama in 1911, 1912, 1913, and 1914, J. F. Duggar and J. T. Williamson (Mahama Col. Sta. Bul. 181 (1914), pp. 153-182).—The chief object of these local fertilizer experiments is given as to ascertain the best combination of fertilizers for corn production on each of the principal soils of the southern half of Alabama.

"From these experiments, most of which were conducted on poor land in dry seasons, it appears that under these conditions reliance should not be placed chiefly on commercial fertilizers in growing corn. Commercial fertilizers have proved much more effective and profitable for cotton than for corn. On nearly all experiments nitrogen, whether employed as cotton-seed meal or as nitrate of soda, afforded a fair increase in the yield of corn. In 60 per cent of these separate experiments the increase from applying 200 lbs. of cotton-seed meal alone per acre was sufficient to afford a profit, even under these unfavorable conditions of soil and climate. Acid phosphate used alone, and in various combinations, usually afforded a small increase in the yield of corn, but this increase was usually not sufficient under these unfavorable conditions to afford a profit. For corn, kainit was even less effective and more generally unfavorable than was acid phosphate.

"When 200 lbs. of cotton-seed meal, applied before planting, was compared with 100 lbs. of nitrate of soda, applied when corn plants were several feet high, nitrate of soda afforded a larger increase. Nitrate of soda afforded, on the average, and in most experiments, a profitable increase in yield. In these experiments commercial fertilizers usually increased the yield to at least as large an extent on land capable of producing 25 to 30 bu. of corn without fertilizer as on poorer land; this suggests that it was the supply of moisture in the richer soils, rather than the fertilizers, which determined yield in these unfavorable seasons. This argues for the plowing under of organic matter in connection with the use of only moderate amounts of commercial fertilizers for corn.

"Considering other experiments, as well as these, the writers make the following general recommendations regarding the fertilization of corn: That so far as practicable stable manure and the remains of soil-improving plants, such as cowpeas, velvet beans, and crimson clover, be preferred to most kinds of commercial fertilizers. That the amounts of commercial fertilizer be limited. That most of the money invested in fertilizers be used in the purchase of nitrogen. That where a pound of nitrogen can be bought in nitrate of soda at the same or at a lower price than in cotton-seed meal, the preference be given to nitrate of soda as a fertilizer.

"That in view of results of unpublished experiments to determine the best time of applying nitrate of soda it is recommended that it be applied as a side application when the corn plants are between $2\frac{1}{2}$ and 4 ft. high. That on soils known to be deficient in phosphoric acid, and especially where heavy applications have not been applied to preceding crops, a moderate amount of acid phosphate be employed. That no investment be made in potash as a fertilizer for corn, especially at the high prices which will doubtless prevail in 1915, except where experience has shown the need of it.

"For the farmer wishing to make only a small investment in the fertilization of corn the following formula, for corn grown under average conditions, is suggested: 100 lbs, acid phosphate, before planting or by the time plants are $2\frac{1}{2}$ ft, high; 60 to 100 lbs, nitrate of soda, applied when the plants are $2\frac{1}{2}$ to 4 ft, high; or, 120 to 200 lbs, cotton-seed meal, applied at the same time as the phosphate, may be substituted for the nitrate of soda."

Local fertilizer experiments with corn in north Alabama in 1911, 1912, 1913, and 1914, J. F. Duggar and J. T. Williamson (Alabama Col. Sta. Bul. 182 (1914), pp. 185-211).—This bulletin gives detailed data of experiments corresponding to the above on each of the principal soils of the northern half of Alabama.

The general conclusions noted above are repeated, except as follows: "On about half of the experiments nitrogen, when employed as cotton-seed meal, gave an increase sufficient to be profitable. Acid phosphate, like cotton-seed meal, gave small increases in most cases, but under the conditions of the unfavorable seasons these increases were profitable in only about 50 per cent of the experiments.

"Nitrate of soda, applied when the corn plants were 2 to 3 ft. high, and on plats which had previously received acid phosphate and kainit afforded, in 72 per cent of these experiments, a profit above the cost of the nitrate. Moreover, the complete fertilizer containing 100 lbs, of nitrate soda, 240 lbs, acid phosphate, and 100 lbs, kainit afforded a profit in 71 per cent of these experiments; but when nitrogen in a complete fertilizer was supplied in the form of cotton-seed meal, the resulting increase was sufficient to afford a profit in only 39 per cent of these experiments.

"In most of these experiments kainit at the rate of 200 lbs, per acre was the least profitable of the fertilizers tested. While this amount of kainit was usually unprofitable when used alone or with only one other fertilizer, yet in many of the experiments it proved slightly profitable as a part of a complete fertilizer containing nitrogen, phosphate, and potash.

Selecting and breeding corn for protein and oil in South Dakota, A. N. Hume, M. Champlin, and H. Loomis (South Dakota Sta. Bul. 153 (1914), pp. 59-78, fig. 1).—This bulletin gives results of selection of corn for high and low protein and for high and low oil content of kernels, covering a period from 1910 to 1913, inclusive.

Comparative average yields of high protein and of low protein corn, 1910–1913, in bushels per acre, and pounds of protein per acre.

| Year. | High protein corn. | | | Low protein corn, | | | | |
|------------------------------|--|---|---|---|--|---|---|---|
| | Yield per acre. | Protein in seed planted. | Protein in corn har- vested, | Yield of protein per acre. | Yield per acre, | Protein in seed planted. | Protein in corn har- vested. | Yield of protein per acre. |
| | | | | | | | | |

The strain of corn selected for high oil content produced in 1911 an average of 86.83 lbs. of oil per acre and in 1912, 216.97 lbs. The percentage contents were 3.47 and 6.1, respectively. The strain selected for low oil content produced 61.59 lbs. of oil per acre in 1911 and 170.66 lbs. in 1912. The percentage oil contents were 3.15 and 5.66, respectively.

As a result of a study to determine the influence of degree of maturity on an oil content of corn it was found that corn harvested on August 15, September 4, and September 19 contained 3.272, 4.982, and 5.523 per cent, respectively, an average composite sample of 40 cars each. It is suggested that the degree of maturity at harvest may account for the wide differences in oil contents of the 1911 and 1912 crops above cited.

Cotton experiments, 1914 (Mississippi Sta. Bul. 169 (1914), pp. 16).—This bulletin gives results of cotton experiments similar to those previously noted (E. S. R., 29, p. 35; 31, p. 136). Results from the central station are reported by E. C. Ewing and J. R. Ricks. A table shows the monthly temperatures and rainfall for 1914. A table giving the results of a variety test shows four early, short staple varieties to range in yield of seed cotton from 1.287 to 1.570 lbs. per acre, eight medium early, big boiled, short staple varieties to range from 1.303 to 1.589 lbs. per acre, and four long staple varieties to range from 1.154 to 1.430 lbs. per acre.

In regard to the values of the different varieties for local production of cotton it is stated "that under average conditions on poor thin land or land of medium fertility, with the boll weevil present, the medium early, big bolled varieties such as Wannamaker Cleveland, Cook, Half and Half (a selection from Cook), and Miller will give better results than the very early, quick maturing varieties, which suffer worse from drought and rust and quit growing early under such conditions. Besides, there does not seem to be as much difference in earliness between the earliest and the latest varieties on thin land as there is between the earliest and the latest varieties on rich land. On rich bottom lands in the presence of the boll weevil, one of the early maturing varieties that does not make too much stalk will be the most satisfactory. In this class there are no better varieties than Trice and Dodd Prolific. In most tests in this State Trice has given better results than Dodd Prolific.

"We regard Express as the best available long staple variety for boll weevil conditions. It is an early inch and three-sixteenths cotton that has given splendid results in the Delta. Unknown is another good early variety that runs from an inch and an eighth to an inch and three-sixteenths."

The results of a test on wilt-infested land are reported, which show that "the wilt-resistant varieties generally gave the best yields in 1912 and 1913, but fell

below the susceptible varieties in 1914. This is on account of the effects of the boll weevil. The wilt-resistant varieties are all late and can not be successfully grown where weevil damage is heavy. At the same time the early varieties that we have found all seem to be rather susceptible to wilt, so the combination, where both wilt and weevils are present to a serious extent, makes cotton growing out of the question. The Covington-Toole wilt-resistant variety has yielded more cotton than any of the other wilt-resistant varieties in all tests that have been made with it at this station."

Cotton planted in rows spaced 3, $3\frac{1}{2}$, 4, $4\frac{1}{2}$, and 5 ft. apart yielded at the rate of 1,660, 1,336, 1,220, 1,200, and 1,176 lbs., respectively, of seed cotton. Cotton spaced 12, 24, and 36 in. in rows 4 ft. apart yielded at the rate of 1,553, 1,403, and 1,153 lbs., respectively, of seed cotton. "The weevils seemed to have gotten all of the squares after August 10."

In tests to prevent rust it was found that a plat receiving no treatment yielded at the rate of 484 lbs, of seed cotton per acre, one receiving 300 lbs, of kainit per acre yielded 1.732 lbs., one receiving 10 tons of barnyard manure in 1911 jielded at the rate of 1.808 lbs., and one receiving 10 tons of barnyard manure in 1913 yielded 1.830 lbs. of seed cotton per acre.

A test of 16 varieties of cotton at the Holly Springs substation, which is reported by C. T. Ames, gave yields ranging from 1.845.2 lbs. to 2.562 lbs. of seed cotton per acre. Cook Alabama Station variety produced the highest yield of seed cotton per acre and was second in percentage of lint (40 per cent), but the staple was only $\frac{3}{4}$ in, in length, the estimated valuation per acre being \$80.95.

The highest valuation per acre, \$96.79, was produced by Durango, with a total estimated yield of seed cotton of 2.111.2 lbs. per acre. Of this, 33.5 per cent was lint having a staple length of $1\frac{\pi}{16}$ in. The longest staple, $1\frac{\pi}{16}$ in., was produced by Sunflower, which yielded at the rate of 2.161 lbs. of seed cotton per acre, producing only 28.7 per cent of lint and having a total valuation of \$74.40 per acre. Half and Half produced the highest percentage of lint, 44.2. measuring $\frac{\pi}{4}$ in. in length, but yielded only 2.304.4 lbs. of seed cotton per acre, which brought the estimated valuation to \$78.40 per acre.

Tabulated results of fertilizer experiments which have been continued for nine years are given. "The use of both nitrogen and phosphorus, either alone or in combination, has given very satisfactory results. Phosphorus hastens maturity. The use of potash, either alone or in combination with the other elements, appears to be unnecessary in these soils. On thin upland the use of 200 to 300 lbs. of an equal mixture of cotton-seed meal and acid phosphate per acre, placed about 3 in. deep under the seed, should give very satisfactory results. On the more fertile soils the quantity of phosphorus may be increased to advantage.

"After leguminous crops phosphate alone at the rate of from 200 to 400 lbs. per acre can be used to profit. Where leguminous crops are to be grown, from 300 to 400 lbs. of rock floats can be used to advantage. Where rock floats is mixed with manure the results are most satisfactory."

Variety tests at the Delta substation, reported by G. B. Walker, showed Express variety to be the most valuable producer.

Express cotton, E. C. Ewing (Mississippi Sta. Circ., 1915, Jan., pp. 8, figs. 2).—This bulletin gives the origin, history, and various characteristics of this variety of cotton. It is noted as being a rather vigorous grower, but not a storm-proof variety, and rather free from fungus diseases. One of the most distinctive characteristics is its earliness. The length of staple is given as about $1\frac{\pi}{10}$ in., and the percentage of lint as about 28.

Cowpea culture, O. O. Churchill. (Oklahoma Sta. But. 105 (1914), pp. 3-22, figs. 8).—This bulletin describes methods of production suitable to Oklahoma conditions and reports results of variety tests for the years 1911, 1912, and 1913, in which the yields of grain ranged from 0 to 10.14 bu, per acre. Notes give characteristics of several varieties during the growing period of 1913. It is stated that the Speckled Crowder, Whippoorwill, and New Era varieties are considered the best for general purposes in Oklahoma.

Kaoliang, a new dry land crop, A. N. Hume and M. Champlin (South Dakota Sta, Bul. 156 (1914), pp. 115-127, figs. 5).—A brief history and description of the plant is given. Results of tests show that at "Highmore the average yield for the five years from 1909 to 1913, inclusive, has been 16.5 but of S. D. 289 and 13.8 but of S. D. 290. The highest yield of S. D. 289 was 19.2 but, in 1910, and the lowest was 10.3 but, in 1911. The average yield of Minnesota No. 13 yellow dent corn for this same period is 12.6 but, showing that the climatic conditions were decidedly severe. At Cottonwood in 1912 kaoliang yielded an average of 23.7 but, per acre as compared with 22.5 but, per acre for Minnesota No. 13 corn. In 1913 the season was so severe at Cottonwood that both kaoliang and corn failed to produce grain, but the kaoliang produced 440 lbs. of dry fodder per acre to 260 lbs. for the corn. In another test kaoliang yielded 2 but of grain and 766 lbs. of dry fodder, whereas corn yielded no grain and 687 lbs. of fodder, thus proving its value in an extremely severe season."

Methods of production suited to South Dakota conditions are described.

Variation and correlation of oats (Avena sativa).—I, Studies showing the effect of seasonal changes on biometrical constants, H. II. Love and C. E. Leighty (New York Cornell Sta. Mem. 3 (1914), pp. 70, figs. 6).—This bulletin describes in detail and gives the results of studies carried out by the station in cooperation with this Department to discover what characters, if any, may be used as a basis for selection and the status of correlation of characters of the oat plant. The variety Sixty Day was used.

Data were gathered during 1908 to 1912, inclusive, and indicate, in regard to the relation of the correlation factors and out production, that "the growth factors influence the developing plants in such a way that tall plants and high yield of grain are found together. . . . It is also interesting and important to note that as the plants tend to increase in height, the number of culms also increases. At the same time it is shown also that the average yield per culm increases as the height of plant increases. This shows the possibility of obtaining plants with many culms that may be high in production, which is rather important, since it is sometimes thought that the average yield of culm would tend to decrease as the number of culms on the plant increased.

"Another important fact brought out by this study is the relation between average weight of kernels and height of plant, and average weight of kernels and total yield. This has an important bearing on the practice of seeding oats... One of the writers has sown hand-picked seed of a number of varieties of oats, and found that in every case the larger yield was obtained from the heavy seed. In another test with oats, in which large and small kernels from the same head were compared, the large seed gave a greater yield."

From the data presented the following conclusions have been drawn:

"Environmental conditions such as exist in different years cause changes in the means. Conditions that generally result in reduction of plant yield also result in reduction of height, number of kernels, and number of culms, but in increase in size of kernels. Yield is reduced by decrease in number of kernels produced, rather than by decrease in their size. Variability decreases with decrease in the means,

"Correlations are more or less responsive to environmental conditions, and may be divided into fluctuating and stable, according to their behavior under differing environments. There are high, positive, and fairly stable correlations between average height of plant and (a) total and average yield. (b) total and average number of kernels produced, (c) average number of spikelets per culm; the correlations between average height of plant and (d) average weight of kernels, (e) number of culms, are fluctuating, being high or low on occasion. There are high, positive, and stable correlations between total yield and (a) culm yield. (b) total and average kernel production. (c) spikelet production, (d) culm production.

"The average kernel weight is not correlated closely and consistently with any other character here considered, except average culm yield, with which the correlation is fairly high and fairly consistent. The average number of spikelets per culm per plant is correlated (a) fairly highly with the average number of kernels per spikelet; (b) apparently very highly with number of kernels per culm; (c) very highly and stably with average height of plant and total yield; and (d) in a fluctuating manner with kernel weight. The correlations between number of culms per plant and (a) height, (b) culm yield, (c) number of kernels, are fluctuating, varying greatly from high to low; between number of culms per plant and (d) total yield they are high, positive, and stable; between number of culms per plant and (e) average kernel weight they are fairly stable and always low."

A bibliography of cited literature is appended.

Variation and correlation of oats (Avena sativa).—II, Effect of differences in environment, varieties, and methods on biometrical constants, C. E. Leighty (New York Cornell Sta. Mem. 4 (1914), pp. 71-216).—The characters of oats dealt with in these studies are height of culm and average height of plant, average length of head per plant, total weight of plant, total weight of culm, average weight of culm per plant, number of kernels, number of spikelets, number of kernels per spikelet of plant, total weight of straw for the entire plant, total weight of straw per culm, average weight of straw per culm of plant, average weight of kernels per plant, diameter of straw, breaking strength of straw, total yield of plant and culm, and average yield of culm per plant.

"The study has been pursued with several purposes in view. One purpose has been to determine the averages, the amounts of variation, and the correlations that exist in various characters of oats. Another has been to determine effects on these characters of various environmental influences. Under the latter head data on the question of methods to be pursued in biometrical work with cereals have been adduced. Correlation has been carefully considered. This was deemed advisable because of the increasing use of, and attention given to, such studies. The correlations taken up have been principally of yield and average weight of kernels with various other characters. . . .

"The first division of this study is a comparison of biometrical constants determined for oat plants and for the culms of the same plants. From the results obtained it may be concluded that, for statistical work with oats, practically the same means and correlation coefficients will be obtained whether plants are used as units or the culms of the same plants are used as units, but that these constants will be slightly greater for the latter method. The standard deviations and coefficients of variability will also be greater when culms are the units. The biometrical results obtained by the several investigators,

whether they worked with culms or with plants, are, however, comparable, with slight reservation, as far as this factor affects the results.

"The second division of this study is a biometrical comparison of varieties of oats. In this study considerable difference is shown in average yield of culm per plant. This is due to the larger kernels produced by certain varieties, since the number of kernels and of spikelets are about the same for the different varieties. There are varietal differences in the height of culm. The average number of kernels per spikelet is greatest in the Sixty Day and smallest in the Early Champion variety. The proportion of straw to grain differs in the different varieties. Considerable difference is found in the amount of variability of different characters of the varieties. The greatest variability, in all characters but one, is found in the Welcome variety, while each of the others is least variable in one or more characters. The coefficients of correlation are usually fairly close together for the different varieties, but some differences occur that may be due to varietal causes.

"The third division of this study is a comparison of biometrical constants determined for oat plants grown in hills and in drills. Regarding all characters here studied, the means are greater for plants grown in hills than for plants grown in drills. The least difference in the means occurs in the cases of average height of plant and average weight of kernels per plant. is greater variability in average yield of culm per plant and average weight of straw in plants grown in hills, but much less variability for plants so grown in average height and average weight of kernels. The variability in number of kernels and number of spikelets is slightly greater for the plants grown in Rather large differences occur in the same variety between the coefficients of correlation determined for the plants grown in the two ways. Whenever large differences in the coefficients of correlation occur, those for the plants grown in hills are always the smaller in amount. The differences due only to the growing condition may amount to more than any varietal differences observed in this work. The constants, then, obtained by different investigators are comparable only in so far as the conditions of growth are comparable.

"The fourth division of this study deals with the effect of different degrees of crowding on biometrical constants of oats. Oat plants grown in very crowded conditions produce but one culm to a plant, but, as more room is given, more than one culm are produced by many plants. The development of plants in most characters is greater in less crowded than in more crowded conditions. Variability decreases with increase in crowding for yield, number of kernels, number of spikelets, and breaking strength of straw; but for height the least variability occurs when crowding is least. In every case when significant differences exist in the correlations between characters in plants grown under different conditions of crowding, there is an increase in correlations produced by more crowded conditions, but there is sometimes a decrease beyond a certain degree of crowding. It has been shown that environmental conditions may influence the degree of correlation of certain characters to a marked extent. Such conditions of environment may make of no significance the so-called varietal and other differences obtained by several investigators."

A bibliography of cited literature is appended.

Irish potatoes, J. C. C. PRICE (Alabama Col. Sta. Bul. 183 (1915), pp. 3-16, figs. 2).—This bulletin describes cultural methods that may be used in Alabama, touching upon soil, varieties, fertilizers, culture, insects and diseases, harvesting, and shipping and storing, both for the early crop and for the fall crop, and also gives results of fertilizer experiments for the years 1911, 1912, and 1913, and of variety tests for these years and 1910. The best yield was ob-

tained with Bliss Triumph in 1912, namely 304 bu, per acre. Trish Cobbler yielded 299,37 bu, per acre in 1911.

In the fertilizer tests the plat receiving a complete fertilizer application in which dried blood was used as a source of nitrogen produced the largest yield, with cotton-seed meal plus acid phosphate, second. Of the single fertilizers the highest yield was obtained with cotton-seed meal, with dried blood second.

Selection and preparation of seed potatoes, size of seed piece and bud variation, A. N. Hume and I. S. Oakland (South Dakota Sta. Bul. 155 (1914), pp. 100-111, figs. 4).—This continues the report of work previously noted (E. S. R., 29, p. 37).

A comparison of yields from seed pieces taken from selected tubers and from culls of two varieties showed in an average of nine cases an increased yield of 5.53 bu, per acre in favor of the selected seed, the average total yield per acre being 114.2 bu. In this test the tubers were cut into quarters, so that the culls represented smaller seed pieces. Early Ohio selected tubers averaged 6.15 oz. and the culls 1.88 oz. in weight. Carmen No. 3 selected tubers averaged 8.4 oz. and the culls 2.08 oz.

A test of the influence of size of seed piece on yield consisted in planting small, medium, and large seed pieces taken from the same tuber.

It is noted that from Early Ohio seed, the average yield from seed pieces of 0.35 oz, was 183.8 bu, per acre, from pieces weighing 1.4 oz., 272.53 bu., and from seed pieces weighing 2.66 oz., 298.59 bu. With Carmen No. 3 seed, the use of seed pieces of 0.35 oz, weight produced an average of 165.66 bu., those of 2.1 oz, weight produced 270.9 bu., and those weighing 4.4 oz, produced 298.23 bu.

As a result of a study of the influence of culls and selected seed upon type and size of progeny it is stated that "under the conditions of this experiment, the use of sizeable seed produced a greater proportion of potatoes of desirable size than the use of culls. The type of potatoes produced from culls used as seed is measurably smaller in the first generation than those produced from selected seed tubers. The results of this experiment furnish quantitative evidence that the use of 'culls' for seed causes potatoes to 'run out.'"

"Not only is the type of tubers produced from selected seed larger than from culls, but also the average weight of tubers produced is greater."

A table shows the comparison of frequencies and weights of tubers produced from culls and from selected seed tubers.

Sudan grass, R. E. Karper (Oklahoma 8ta. Bul. 103 (1915), pp. 3-14, figs. 3).—This bulletin describes methods of production of Sudan grass suitable for Oklahoma conditions, together with some data on cultural tests. The results of planting on eleven different dates, between April 15 and July 6, 1914, show early May, from the sixth to the fourteenth, to be the most favorable time to plant Sudan grass for hay.

"It will be observed from the data given that the 6-in, rows gave larger yields than the 21-in,, and the 42-in, rows gave by far the largest yields. The increase of the 6-in, rows over the 21-in, rows was due to the fact that the crab grass and other weeds grew up on the 21-in, plat and the rows were not of sufficient width to permit the use of the cultivator to keep them down, while the 6-in, rows were close enough together to smother out the majority of the weeds. The 6-in, and 21-in, plats did not come on again after the first cutting was made on account of lack of moisture. The plats of 42-in, rows made two cuttings, which also helps account for their larger yields."

In testing the proper time to cut Sudan grass for seed production larger yields were obtained by cutting on July 28 than on July 14, 17, or 22, the largest yield

being 350 lbs, per acre. Wide spacing between rows, namely, 42 in., produced larger yields of seed than 6-in, spacing.

A table reports analyses of Sudan grass and other forage crops generally grown in Oklahoma. The uses and value of the Sudan grass crop for soiling and silage, pasture, catch crop, rotation crop, and forage are briefly noted.

The commercial production of sugar-beet seed in Utah, F. S. Harris (*Utah Sta. Bal. 136* (1915), pp. 47–58, figs. 6).—In describing the methods for the production of sugar-beet seed in Utah the topics covered include getting the "mother seed," siloing, planting, caring for the crop, harvesting and threshing, cleaning, yield, and cost. Data from crops grown in 1912, 1913, and 1914 show that beets from home-grown seed were higher in sugar content than the beets from imported seed, although the yield from the imported seed was somewhat higher. The average weight of seed produced by mother beets for the years 1905 to 1913, inclusive, ranged from 263.7 to 722.6 gm, per beet.

In testing different methods of preserving mother beets during the winter in the rows where they grew it was found that covering with manure 6 in, deep was much more satisfactory than covering with 8 in, of straw or with 8 in, of straw and 4 in, of soil, or covering by running a plow along the row. In the latter case none of the beets survived the winter, while from the manure-covered row 197 beets lived and produced 26 lbs, of seed.

The average seed production at the station for 1912, 1913, and 1914 is given as 1.190, 1.354, and 1.571 lbs, per acre, respectively, and the estimated cost of production as \$95 per acre.

Sweet potato growing in the cotton belt, H. C. Thompson (U. S. Dept. Agr., Office Sec. Spee. [Cire.], 1915, Mar. 9, pp. 8).—Brief notes on cultural methods and uses are given.

Types and varieties of Maryland tobacco, W. W. Garner and D. E. Brown (Maryland Sta. Bul. 188 (1914). pp. 135-152, figs. 4).—This bulletin describes the characteristics of Maryland types of tobacco, together with some commercial qualities, including the varieties Maryland Broadleaf, Maryland Narrowleaf, Maryland-Connecticut Broadleaf, Maryland-Burley Broadleaf, and Maryland Mammoth. Instructions for producing and saving the seed under bag and for the selection of seed plants are given.

Data show the results of variety tests and the proportion of leaf to stalk in different varieties, conducted in cooperation between the station and this Department. "The results of these tests indicate that the Maryland-Connecticut and the Maryland-Burley are desirable types for growing on the lighter soils, which produce tobacco of fine quality, while the Mammoth gives promise of proving at least equal to the best varieties on these light soils and decidedly superior to all other varieties on the heavier, more fertile tobacco soils on which other varieties produce tobacco of comparatively poor quality." The Maryland-Burley Broadleaf and Maryland Mammoth produced a considerably lower proportion of stalk than the other three varieties.

The quality of grass and rape seed found in Maryland markets in 1913, C. P. Smith (Maryland Sta. Bul. 189 (1915), pp. 153-180).—This bulletin completes the published results (E. S. R., 31, p. 438) of 1913 inspection work amongst the Maryland field seed vendors and also presents the text of the Maryland seed law of 1914. The seeds covered by the work in this bulletin are timothy, blue grass, German millet, orchard grass, redtop, and Dwarf Essex rape.

[Seed inspections], A. Atkinson and B. W. Whitlock (Montana Sta. Bul. 101 (1914), pp. 165-176, fig. 1).—The first annual report of the State Grain Laboratory gives results of germination and purity determinations for 2.266 samples of seeds. The largest number of varieties of weed seeds, namely, 60,

was found in 549 samples of alfalfa; 42 varieties were found in 99 samples of timothy; 31 in 58 samples of red clover; and 31 in 260 samples of oats, and smaller numbers in the remaining 18 kinds of seed examined.

Seed tests made at the station during 1914, M. T. MUNN (New York State Sta, Bul. 394 (1915), pp. 27).—This bulletin gives results of analyses of 303 official samples of seed and 1.155 samples sent in by correspondents in 1914, and discusses the method of analysis and requirements of the seed law and its significance to New York farmers.

Of the official samples 10.9 per cent showed violations of the law, these being mainly alsike clover samples contaminated in the field with other crop seeds. However, "the present seed law affords only a partial protection to the purchasers of seed, since it does not require a reasonable freedom from dodder or other noxious weeds or from inert matter."

Analysis of the correspondents' samples "indicate that the number of kinds of weed seeds found in crop seeds for sale in this State is increasing."

Purity of farm seeds in 1914, F. H. Hall (New York State Sta. But. 394 (1915), popular ed., pp. 4, fig. 1).—A popular edition of the above.

Agricultural seed, G. P. Burns (Vermont Sta. Bul. 183 (1914), pp. 269-294).—This bulletin gives the text of the Vermont seed inspection law and shows in tabular form the results of examining 234 official samples and about 100 voluntary samples. Alfalfa, alsike clover, corn, millets, red clover, redtop, and timothy seed as sold in Vermont was compared with the United States standard, a large part of the samples other than redtop being equal to or better than the standard. Eighty-five per cent of the seed other than redtop was of standard quality as regards purity and 88 per cent as regards viability.

Suppression of weeds among pineapples by arsenite of soda spray, F. G. Krauss (Hawaii Sta. Press Bul. 48 (1915), pp. 8, figs. 2.)—This describes methods and apparatus used in successfully destroying weeds on pineapple plantations by the use of arsenite of soda spray, the most successful solution being 5 lbs. of white arsenic, 5 lbs. of carbonate of soda boiled in 10 gal. of water, and additional water to make 100 gal. The total cost of the spraying is given as \$2.30 per acre.

HORTICULTURE.

[Horticultural investigations in Guam], J. B. Thompson (Guam Sta. Rpt. 1914, pp. 9-14, pls. 2).—Notes are given on the culture and adaptability of many of the common vegetables under conditions in Guam. Thus far the ordinary commercial varieties of tomatoes have failed to grow. Results during the past season with the Texas Bell. a strain of the cherry tomato, indicate that this variety will succeed and that a fixed type of tomatoes may be developed for Guam by selecting and breeding from the largest fruited plants of Texas Bell.

The propagation of mangoes at the station (E. S. R., 31, p. 441) was continued during the year, and a limited number of inarched plants have been distributed to planters. It was demonstrated that by using proper precautions to prevent undue evaporation large mango trees may be successfully transplanted.

Report of the acting horticulturist, C. J. Hunn (Hawaii Sta. Rpt. 1914, pp. 29-35, pls. 2).—In a previous report (E. S. R., 30, p. 841) on the work of breeding papayas with the view of eliminating male trees, one type was secured which yielded 94 per cent fruit-bearing trees out of 343 F₂ trees. Additional data show that out of 454 of these F₂ trees which has fruited 95.37 per cent were fruit bearing, thus indicating that with the continuation of the breeding

work the staminate type will be eliminated. During the course of breeding work an elongated fruit has increased in percentage which gives promise of the ultimate development of a pure strain of uniformly cylindrical fruits of good quality. The future breeding work is to be confined to the elongata type.

Attention was also called in the previous bulletin on papayas to authenticated instances in which male papayas had been changed to fruiting trees by cutting the tops off the male trees. Such an experiment was conducted at the station by V. S. Holt during the past summer, in which the tops were removed from 22 sterile staminate trees selected from different varieties. Two of these trees, which had been selected from the above-noted type which yielded 95.37 per cent fruit-bearing trees, did become fruit-bearing trees when the top grew out again. In lieu of more definite knowledge this phenomenon is attributed to the preponderant tendency to fruit bearing in the type from which the two trees were selected.

Data have been accumulated showing the various types of trees in the mango and avocado orchards. The average age and time of bearing of mango seedlings was 6 years 3 months; budded mangoes, 3 years 8 months; inarched mangoes, 2 years 10 months; avocado seedlings, 7 years; and budded avocados, 2 years 11 months.

Heavy paper bags have been used with success in protecting ripening fruit from the attacks of the Mediterranean fruit fly. The individual fruits ripen more uniformly, but lack the color of those exposed to the sun. Several varieties of the Indian mango have been found to be practically immune to the attacks of the fruit fly.

The work of breeding ornamental hibiscus plants (E. S. R., 30, p. 838) has been continued. A number of new varieties has been secured, one of which, a yellow variety, is described. A description is given of a spineless caetus which was collected by the station several years ago in Honolulu and which is believed to be worthy of attention as an ornamental hedge and as a fodder plant. The wampee (Clausena lansium), a tree whose edible berries are highly esteemed by the Chinese, is also described. About a dozen of these trees are in bearing in Honolulu.

A further report is given on two lots of pineapple seedlings which were secured from a single fruit in each case (E. S. R., 30, p. 838). The plants continue to show a great variation in height, spread of foliage, color, and other characters. A number of these plants give promise of developing into superior plants, and the best of the seedlings are to be grown under field conditions to determine the character of the fruit.

Report of the superintendent of the rubber substation, W. A. Anderson (Hawaii Sta. Rpt. 1914, pp. 51-56).—An experiment was started in 1912 to determine the feasibility of transmitting high yielding properties of individual Ceara rubber trees through cuttings. Cuttings of good yielding trees planted in February, 1912, and grown under cultivation with companion crops of broom corn and roselle were tapped with a single cut in January, 1914. The new growth on these trees, 1 ft. above the original cutting, averaged 10.8 in, in circumference. They yielded 16 oz. of washed rubber from one tapping of one cut per tree. This yield compared favorably with the average reported from 6-year-old unselected trees, tapped in 1912. The yield from the different trees was more uniform than on the plantations as a whole. The results thus far secured indicate that propagation by cuttings will assure more desirable latexyielding qualities than propagation by seedlings.

The work on roselle as a companion crop with rubber shows that large yields can be obtained. To be profitable, however, the fresh fruit should sell for from 3 to 4 cts. a pound, whereas the highest price now paid for drying purposes in

a limited market is at the rate of $3\frac{1}{4}$ cts, per pound. Precautions must be used against cutworms and some means of artificially drying the fruit must be provided. Under present conditions the fruit can be seeded most economically as it is picked. It has been found possible to continue some of the plants for a second season's crop.

Fertilizer experiments conducted with a thousand rubber trees, in which nitrogen, phosphoric acid, and potash were used both alone and in combination, are reported. The best results, both in yield of latex and growth of trees, were obtained by using superphosphate and potassium sulphate without any nitrogen. At the same time the results are not sufficiently pronounced to indicate that fertilizers can be used with profit on rubber trees in Nahiku, the district where the tests were made.

The home garden in the South, II. C. Thompson (U. 8. Dept. Agr., Farmers' Bul. 647 (1915), pp. 28. figs. 8).—This publication, which has been prepared with special reference for use in the South, gives suggestions as to the location, plan, and arrangement of the garden, the soil and its preparation, manures and fertilizers, the seeds and plants to use, together with brief descriptions of the methods of handling the more important vegetables. Suggestions are also given relative to varieties suitable for securing a continuous supply of vegetables throughout the year.

Alaska's pomological resources and outlook, C. C. Georgeson (*Proc. Amer. Pomol. Soc.*, 1913, pp. 79-82).—A short account relative to the adaptability of various orchard and small fruits to Alaskan conditions.

The present status of Canadian pomology, W. T. Macoun (Proc. Amer. Pomol. Soc., 1913, pp. 64-79, pl. 1).—An account of the orchard industry in Canada in which consideration is given to the kinds of fruit grown in the different districts, fruit breeding, methods of culture and marketing, and government aid to fruit growers. Data are given showing the number of bearing and nonbearing fruit trees for each Province in 1910, exports of various fruits from Canada in 1912-13, and lists of the principal varieties of fruits grown, including a list of fruits of Canadian origin.

Fruit in the North, D. W. Buchanan (*Proc. Amer. Pomol. Soc.*, 1913, pp. 55-58).—A short account of the adaptability of various deciduous fruits to conditions in Manitoba.

[Report of the] division of horticulture (Washington Sta. Bul. 118 (1914), pp. 24-26).—The orchard pollination study, which is being conducted at Pullman and in several private orchards, indicates that with one or two exceptions the varieties of apples blossom so nearly at the same date that interpollination can take place between any of the common commercial apples. The indications are that while several of the apple varieties may under certain circumstances be partially or entirely self-sterile, these same varieties may be considered fairly successful when grown in solid blocks in the thickly planted orchard sections.

A study of the keeping quality of fruit, especially apples, indicates thus far that fruit developed on trees that received an excess of water have their keeping qualities greatly impaired. The tissue is soft, easily broken, and goes down quickly in storage. Fruit developed on trees receiving approximately the correct supply of water for development of medium-sized firm fruit for the variety have the maximum keeping quality. Fruit developed on trees receiving less water than that necessary for the development of medium-sized fruit is inferior in quality and appearance and tends to shrivel before decaying.

Winter work in orchards, M. P. Somes (Missouri Fruit Sta. Circ. 7 (1914), pp. 3).—This circular calls attention to work, such as pruning, spraying for

scale, worming for borers, etc., that may be carried on during the winter period of idleness,

Does spraying pay? M. P. Somes (Missouri Fruit Sta. Circ. 8 (1914), pp. 3).—In this circular the author presents data taken from experiments made by the station to show that it pays to spray even single trees. Attention is called to the fact that spraying as it is too often done does not pay, and brief general suggestions are given relative to proper methods of spraying.

[Orchard heating], A. J. Cook (Bicn. Rpt. Cal. State Com. Hort., 6 (1913-14), p. 8).—In a brief summary dealing with observations of the freeze in the California citrus region in January, 1913, the author concludes that orchard heating is indispensable, and that a good heating system with sufficient oil and help available on call will protect against the lowest temperature ever yet known in the citrus belt.

Apple growing in California, G. P. Weldon (Sacramento: State Com. Hort., 1914, pp. 124, figs. 58).—A practical treatise designed to cover the more important phases of apple culture with special reference to California conditions. The introductory chapter gives the statistics of the apple industry in that State.

"Iowa 403," a new seedling apple, S. A. Beach (Iowa Sta. Circ. 18 (1914), pp. 3).—This circular gives the history as far as known and description of one of the promising seedling apples originated at the station which has been named "Iowa 403." The apple as here described is dark red, attractive when well-colored, and desirable for either cooking or dessert uses. The test thus far indicates that the tree is a reliable cropper under adverse climatic conditions. The variety is now offered for distribution to nurseries.

The technical description of apples, J. K. Shaw (Massachusetts Sta. Bul. 159 (1914), pp. 73-90, pls. 4, figs. 3).—In this bulletin the author has compiled in a definite and systematic manner various methods and terms used in the systematic and commercial description of apples, both trees and fruit. The bulletin is intended for the use of students and investigators in connection with a text-book or reference work on systematic pomology. A number of reference works are listed.

The varieties of plums derived from native American species, W. F. Wight (U. S. Dept. Agr. Bul. 172 (1915), pp. 44).—This bulletin comprises a record of American varieties of plums including hybrid forms. The record as a whole shows the species to which the variety belongs, its geographic origin, time of introduction, and the introducer. Plant material has been examined whenever procurable. References are given to persons, institutions, and localities furnishing material as well as to other sources of information, much of which was found in The Plums of New York (E. S. R., 27, p. 40).

Plum culture in Ontario, F. M. CLEMENT (Ontario Dept. Agr. Bul. 226 (1914), pp. 32, figs. 12).—This bulletin discusses the present status of the plum industry in Canada as a whole and the cultural methods of the most successful growers in Ontario, describes the more important commercial varieties, and offers suggestions relative to future development.

The native persimmon (Diospyros virginiana), W. F. FLETCHER (*Proc. Amer. Pomol. Soc.*, 1913, pp. 48-50).—A short account of the native persimmon with reference to its history, characteristics, distribution, propagation, and culinary uses.

Studies on native fruits.—I, Grapes, musts, wines, ciders, and vinegars, J. Puig y Nattino (Min. Indus. [Uruguay], Insp. Nac. Ganadería y Agr. Bol. 10 (1914), pp. 62, figs. 9).—This is the first of a series of studies on the fruits and fruit products of Uruguay. The present bulletin contains analytical data

showing the composition of a large number of varieties of grapes, with special reference to the density of the must and the content of sugar, acid, and ash. Analyses are also given of wines, vinegars, and ciders derived from the grapes, together with data showing the average size of fruit of each variety and the proportion of stems, skins, and seeds.

Studies on native fruits.—II, Peaches, pears, and plums, J. Puic y Nattino (Min. Indus. [Uruguay], Insp. Nac. Ganaderia y Agr. Bol. 13 (1914), pp. 77. pls. 86, figs. 10).—In continuation of the above work data are here presented for different varieties of peaches, pears, and plums relative to their sugar, acid, protein, and ash content, the average weight of fruit, and the proportion of waste material. Outline drawings are given showing the general shape of many of the varieties.

A basis for the future classification of the mango, F. W. Popenoe (*Proc. Amer. Pomol. Soc., 1913, pp. 41–47, pls. 2, fig. 1*).—In this paper the author presents suggestions relative to the description and classification of mangoes, together with a bibliography of literature dealing with mangoes.

The handling of Porto Rican oranges, grapefruit, and pineapples, C. W. Mann (Porto Rico Bd. Agr. Expt. Sta. Bul. 7 (1914), pp. 59, figs. 24).—During the shipping season of 1913–14 the losses from decay in cargoes of oranges, grapefruit, and pineapples shipped from Porto Rico to New York were so severe that the U. S. Department of Agriculture conducted an investigation in behalf of Porto Rican growers to determine the causes of this decay. Some data are presented showing the percentage of decay found in several lots of grapefruit and oranges, and an account is given of an inspection made in Porto Rico relative to methods of handling the fruit in groves and packing houses and in transportation to the steamers, together with recommendations for improving these practices as well as improving the methods of handling fruit during transportation and in New York. The results of the investigation as a whole indicate that as with the work in California and Florida (E. S. R., 20, p. 43; 30, p. 841) there is a close relation between the occurrence of decay and the character of the methods employed in picking, packing, and transporting fruit.

Statistical data covering several years are given showing the growth of the citrus and pineapple industries in Porto Rico.

[Experiments on the applicability of cold storage to various tropical fruits], E. V. Wilcox (*Hawaii Sta. Rpt. 1914*, p. 23).—A brief statement of progress. The work has been noted more in detail from another source (E. S. R., 32, p. 439).

Tropical fruits in the Philippines, P. J. Wester (*Proc. Amer. Pomol. Soc.*, 1913, pp. 88-91).—A short account of the more important fruits and the present status of fruit growing in the Philippines.

[Cacao investigations at River Estate], P. CARMODY (Bul. Dept. Agr. Trinidad and Tobago, 13 (1914), No. 84, pp. 312-319).—Data are given showing the comparative yields for a 4-year period of 100 individual cacao trees. The results, as a whole, indicate an inherent productivity for individual trees. Data are also given showing the yields on the various cacao manurial plats for the 4-year period 1910-11 to 1913-14.

Cocoa, C. J. J. van Hall (London: Macmillan and Co., Ltd., 1914, pp. XVI+515, figs. 140).—A handbook on cacao in which the successive chapters discuss the history of the cocoa industry; geographical distribution and climatic conditions; the chemistry of cacao and cacao soils; the botanical characteristics of the cacao plant; varieties of cacao; the cultivation of cacao; fermentation, washing, and drying; diseases and enemies; cacao growing countries; commerce; and notes on the cocoa and chocolate industry.

Report of the coffee testing gardens at Bangelan, T. Wurth (Jaarb, Dept, Landb., Nijv, on Handel Nederland, Indië, 1913, pp. 43-57, pls. 3).—A progress report on cultural and selection studies with various kinds of coffee.

Data secured with reference to the sterility or self-fertility of coffee blooms indicate that a certain amount of fruit was set when the blossoms were protected from outside pollination. Tests are to be conducted further to determine whether the seed from close pollinated fruit is viable. Data are given on the yields secured in 1911, 1912, and 1913 from seedling plants selected from various mother trees. A test which has been conducted for three seasons to determine whether Robusta and Quillou coffees can be grown better as single-stem plants or as multiple-stem plants has thus far shown very little difference in yield. In some topping experiments with these two varieties the trees were headed back at different heights ranging from 6 to 12 ft., and the results indicate that the higher the trees are topped the greater the yield of coffee. For the three years of tests untopped trees gave somewhat better yields than topped trees. In a test of the viability of coffee seed placed in storage, samples of Robusta coffee seed which had been stored in dampened powdered charcoal for a period of five months give a total germination of 67 per cent.

[The influence of fruit flies on the quality of coffee], E. V. Wilcox (Hawaii Sta. Rpt. 1914, p. 22).—Analyses were made of samples of coffee from coffee cherries uninfested with fruit fly, badly infested with fruit fly, and also from half-ripe cherries taken four or five days before they would be completely ripe. No chemical differences in the composition were noted in the different samples. Coffee was prepared for drinking from all the samples by three different methods and was submitted to several persons for their opinion as to the flavor and other qualities of the different samples. The various reports agreed that the sample from the infested fruit was slightly insipid and poor in quality, while that from the fruit not quite ripe was best in quality. The deterioration in quality in ripe coffee berries is attributed to the fermentation of the whole cherry which rapidly develops a putrefactive odor.

A further test was made to determine whether infestation with the fruit fly might cause a loss of weight in coffee. It was found that the weight of berries from infested coffee cherries immediately after pulping was 5 per cent less than that of berries from uninfested fruit. When the coffee came to a constant weight and was considered dry, however, the weights of the two lots were the same. Hence it appears that little or no loss in the weight of the coffee berry is caused by infestation by the fruit fly.

The palms cultivated in the open air in the gardens of Italy, G. ROSTER (Bul. R. 80c. Toscana Ort., 3, ser., 18 (1913), Nos. 2-3, pp. 36-46; 4, pp. 82-93, fig. 1; 5, pp. 107-113, pl. 1; 6, pp. 131-135, pl. 1; 7, pp. 153-158, pl. 1; 8, pp. 178-181; 9, pp. 194-200; 10, pp. 218-225, pl. 1; 12, pp. 265-269, pl. 1; 19 (1914), Nos. 1, pp. 13-17, pl. 1; 3, pp. 54-61, pl. 1; 5, pp. 110-113; 6, pp. 124-129, pl. 1; 7, pp. 150-155; 8, pp. 169-176; 9, pp. 191-193; 10, pp. 213-224, pl. 1; 11, pp. 239-244; 20 (1915), Nos. 1, pp. 12-19; 2, pp. 32-43).—This comprises an enumeration of those species of palms which are cultivated in Italy under open garden conditions. A summary is given of the more important vegetative characters of the different species. Only those species are considered at length which have been observed growing in more than one locality.

The present status of the different varieties of walnuts, W. W. Fitzgerald (Mo. Bul. Com. Hort. Cal., 3 (1914). No. 12, pp. 493–500, fig. 1).—Notes are given on the varieties of walnuts grown in California with reference to their general characteristics, bearing habits, commercial value, blight resistance, etc.

The use of commercial fertilizers in growing carnations, H. B. Dorner, F. W. Muncie, and A. H. Nehrling (Illinois Sta. Bul. 176 (1914), pp. 365-386,

figs. 3; Bul. 176, 4bs. (1914), pp. 4).—The experiments here reported in detail were conducted to determine the feasibility of the complete or partial substitution of commercial fertilizers for manure as a source of plant food for carnations.

In the first experiment, extending over a period of three years, commercial fertilizers in various proportions and amounts were applied to different sections of benches in the greenhouse and the effects on the number and quality of the flowers noted. In the second experiment, extending over two years, the production of sections treated with manure was compared with that from sections treated with commercial fertilizers. A uniform soil was selected for all sections.

The results of the work as a whole lead to the conclusion that dried blood (or ammonium sulphate instead), acid phosphate, and potassium sulphate may safely be used in the culture of carnations. On the brown silt loam used in the experiments nitrogenous fertilizers have produced a consistent increase in production. Nitrogen may be regarded as the limiting element of growth. There are indications that the addition of acid phosphate to a nitrogenous fertilizer will cause a still further increase in production and an improvement in quality as well. The quality of flowers produced with commercial fertilizers as measured by various factors is equal to that of those grown with manure. The time of maximum crop production was independent of the kind of fertilizer used and its time of application. Injury from overfeeding results from the excessive use of potassium sulphate and dried blood. On the other hand, large quantities of acid phosphate seem to improve the quantity and quality of the flowers.

FORESTRY.

Fourth annual report of the state forester to the governor, 1914, F. A. Elliott (Ann. Rpt. State Forester Oreg., 4 (1914), pp. 63, figs. 10).—A progress report on forest administration in Oregon. The introductory chapter briefly reviews the forest resources of the State. The succeeding chapters deal with forest taxation, organization of protective work, fire losses, improvement work, slash disposal, federal cooperation under the Weeks Law, compulsory patrol law, association and state patrols, recommendations for improving protective work, and financial statements.

Report of the forest branch of the department of lands for the year ending December 31, 1914 (Brit. Columbia Rpt. Forest Branch Dept. Lands, 1914, pp. 63, pls. 6, figs. 3).—A report on forest administration in British Columbia in which information is given relative to forest organization, forest revenues, timber sales and leases, forest reconnoissance, the lumbering industry, including export and import statistics, minor forest industries, railway permits, regeneration and yield studies, land classification, grazing, forest protection, etc.

Annual progress report upon state forest administration in South Australia for the year 1913–14; W. Gill (Ann. Rpt. State Forest Admin. So. Aust., 1913–14, pp. 11, pls. 7).—A brief progress report on state forest administration in South Australia, including a financial statement for the year ended June 30, 1914. Data are given showing the area of forest reserves and plantations, areas inclosed for planting operations, the year's planting and other forest operations, and revenues and expenditures, including a comparative statement for the past 37 years.

The utilization of chemical locality factors by forest plants, H. BAUER (Forstw. Centbl., n. ser., 36 (1914), Nos. 11, pp. 549-578; 12, pp. 610-621).—In this article the author reviews the knowledge relative to the utilization by plants of residual chemical soil nutrients and of supplementary fertilizers, with

special reference to his work and that of Ramann, dealing with the variation in time of nutrient assimilation among forest trees (E. S. R., 26, p. 443; 27, p. 630). Results of recent analytical studies of red alder and elm trees are presented in tabular form and discussed in connection with previous investigations.

A montane rain-forest.—A contribution to the physiological plant geography of Jamaica, F. Shreve (Carnegie Inst. Washington Pub. 199 (1914), pp. 110, pls. 29, figs. 18).—In this work the author presents the results of a study of the general physiological plant geography, as well as investigations on transpiration and growth in typical rain-forest forms occurring in the Blue Mountains in Jamaica.

A conspectus of North American firs (exclusive of Mexico), W. H. LAMB (*Proc. Soc. Amer. Foresters, 9 (1914), No. 4, pp. 528–538, figs. 15)*.—The purpose of this paper is so to define and illustrate the distinguishing characteristics of North American firs that the group may be easily distinguished by forest officers.

A bibliography of reference literature is appended.

Forest planting in Arizona and New Mexico, G. A. Pearson (Proc. Soc. Amer. Foresters, 9 (1914), No. 4, pp. 457-478).—This article embraces the results at present available from the efforts toward solving the reforestation problem on the National Forests in the Southwest. The data here presented are based on general planting operations in the Southwest and intensive experiments at the Fort Valley Experiment Station and at the Fort Bayard Nursery.

Reforestation of brush fields in northern California, R. H. BOERKER (Forestry Quart., 13 (1915), No. 1, pp. 15-24).—A descriptive account of reforestation operations conducted on the Lassen National Forest, northern California, including information relative to costs of reforestation.

Charcoal as a means of solving some nursery problems, G. A. Retan (Forestry Quart., 13 (1915), No. 1, pp. 25-30).—An experiment conducted in the nursery at the Pennsylvania State Forest Academy in the use of charcoal as a dressing for forest seed beds is described. Included in the experiment was a comparative test of charcoal and commercial fertilizer.

Beds treated with charcoal gave a larger germination percentage than untreated beds. A constant observation of the beds seemed to indicate that where the proportion of charcoal in the bed is large there is less "damping-off." Thus far no definite results have been secured with reference to the comparative value of charcoal and the commercial fertilizer.

Organization of forest fire control forces, C. Du Bois (*Proc. Soc. Amer. Foresters*, 9 (1914), No. 4, pp. 512–521).—A discussion of methods of organizing and directing fire protective bodies.

Tables for determining profits in forestry, W. D. Sterrett and W. B. Barrows (Forestry Quart., 13 (1915), No. 1, pp. 12-14).—A table is here given and discussed which aims to show for quite a wide range of yields and stumpage prices what will be the net profit and corresponding compound interest rate on a number of different initial investments.

A practical system of logging cost accounting, S. B. Detwiler (Forestry Quart., 13 (1915), No. 1, pp. 8-11).—A logging cost accounting system is described which was used by the author with satisfactory results and is believed to be adapted to nursery work and other lines of forestry.

DISEASES OF PLANTS.

Report of the experiment station for plant diseases, 1913, H. C. MÜLLER ET AL. (Ber. Agr. Chem. Kontroll u. Vers. Stat. Pflanzenkrank. Prov. Sachsen, 1913, pp. 63-73).—This contains brief notes of plant diseases as reported by

correspondents, and of investigations at the experiment station for the province of Saxony, referring to diseases of cereal, root, and tuber crops; also of tests made with fungicidal applications and apparatus for their employment.

A list of 1913 publications is also given.

Mycological notes, B. G. C. Bolland (Agr. Jour. Egypt, 3 (1913), No. 2, pp. 123-126).—Seed wheat soaked in copper sulphate solution of 0.5 to 10 per cent strength for periods varying from 1 to 30 minutes and germinated showed the increasingly injurious effects of concentrations greater than 0.5 per cent, and of exposure for longer periods than 10 minutes for the weakest solution and of 5 minutes or even 1 minute for higher concentrations.

A fruit spot on apples originating at Constantinople and examined at Alexandria was diagnosed as due to Cylindrosporium pomi.

Fungi causing disease in Surinam, J. Kulper (Rec. Trav. Bot. Néerland., 11 (1914), No. 1, pp. 44–53, figs. 9).—Noting briefly Cercospora cofficiola spotting leaves and aborting grains in Coffea, Leptosphæria cofficiola in brown lenf spots on coffee, Mycosphærella coffeæ causing less leaf damage than formerly in the same plant, and M. criodendri, described as a new species on young plants of Eriodendron anfractuosum, the author also mentions as saprophytic or more or less parasitic, Sphærotheca pannosa on roses, Phyllosticia theobromæ on cacao leaves, P. coffectola as a secondary fungus in leaf spots on coffee, Ascochyta atropa on leaves of Phascolus mungo, Cercospora personata on leaves of Arachis hypogæa, C. rosicola on roses imported from Europe, and C. riticola on leaves and fruits of grape.

A review of some Philippine plant diseases, C. F. Baker (*Philippine Agr. and Forester*, 3 (1914), No. 7, pp. 157, 164).—The author briefly notes the occurrence, distribution, and in some instances the effect produced by fungiattacking a considerable number of cultivated plants in the Philippines.

A new North American Endophyllum, J. C. ARTHUR and F. D. FROMME (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 172).—The authors describe a species of Endophyllum which is reported as occurring on species of Callirhoe, Sidalcea, and Althea in Kansas, Nebraska, Colorado, and Wyoming. This is believed to be the first North American rust which is assigned to the genus Endophyllum, as shown by germination tests.

Studies in the genus Entorrhiza, C. Ferdinandsen and Ö. Winge (Dansk Bot. Arkir, 2 (1914), No. 1, pp. 13, figs. 8).—According to the authors the genus Entorrhiza has been generally considered a near relative to the Ustilagineae, although Brefeld (E. S. R., 27, p. 746) has advanced the opinion that it belongs to the Ascomycetes, the ascus form of which is unknown.

As a result of their studies they have come to the conclusion that Entorrhiza belongs in the neighborhood of the Ustilagineæ and may be considered as a primitive type of this group. All of the species are said to live in the soil and spread their spores by aid of the water, while the genuine Ustilagineæ are adapted to aerial life. Different species of Entorrhiza have been recognized which are parasitic on the roots of different species of Juncaceæ and Cyperaceæ.

A bibliography is given.

Effect of temperature on Glomerella, C. W. Edgerton (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 174).—The author reports on the species or strains of the genus Glomerella which respond differently to different temperatures. One form, the one found on bean, Colletotrichum lindemuthianum, is very susceptible to high temperatures, growth ceasing at about a temperature of 31° C. (87.8° F.). This, it is believed, will explain why this form is not prevalent during the hot part of the summer or in warm climates. The different strains of Glomerella are said to fall into several classes in regard to the temperature

factor. Nearly 50 different cultures have been grown at temperatures ranging from 14 to 37° C.

Cultures of Uredineæ in 1912, 1913, and 1914, J. C. Arthur (Mycologia, 7 (1915), No. 2, pp. 61–89; abs. in Science, n. ser., 41 (1915), No. 1048, p. 172).—In continuance of previous investigations (E. S. R., 26, p. 645) the author has reported a large number of trials made, in which about 70 successful infections were produced, involving about 30 species. About half the successful cultures confirm previous work with the same species. A large number of the remainder extended knowledge regarding the species, some showing that what had been considered valid species may be reduced to synonymy, while a few cultures demonstrated the full life history of species never before cultured.

Disease in oat seedlings, E. Voges (Deut. Landw. Presse, 41 (1914), Nos. 64, pp. 773, 774, figs. 3: 65, p. 782).—A study of nematodes in oats, also of a fungus (Fusarium didymum) found in the lower portions of the stem, is said to show that the former cause comparatively little damage to the crop, but that in the younger stages the latter may cause considerable injury when its presence is associated with bad soil conditions as regards texture, drainage, and balancing of fertilizers.

A test of Indiana varieties of wheat seed for fungus infection, G. N. Hoffer (*Proc. Ind. Acad. Sci., 1913, pp. 97, 98*).—The author, reporting investigations of 34 varieties of seed wheat, states that 14 were free from fungi, 13 were infected with a Fusarium, 4 showed the presence of a Macrosporium, and 3 contained both these fungi.

Resistance of different varieties of wheat to rust, F. Scurti and V. Sica (Ann. R. Staz. Chim. Agr. Sper. Roma, 2. ser., 7 (1914), pp. 33-56).—The authors, reporting on experiments continued for three years on varieties of wheat, state that the results thus far tend to confirm the conclusions announced by Comes (E. S. R., 30, p. 242) regarding a general relation between decrease of acidity in the cell sap and diminution of resistance to disease in plants which increases under cultivation.

Beet rust, J. Eriksson (Rev. Gén. Bot., 25 bis (1914), pp. 247-258, figs. 2).— The author holds that Uromyces betw, which causes beet rust (decreasing the sugar content of the root) may remain latent during the winter in the form of intracellular mycoplasm. Exclusion of seed originating in districts not known to be free from this disease is recommended.

Irish potato scab (Oospora scabies) as affected by fertilizers containing sulphates and chlorids, S. D. Conner (*Proc. Ind. Acad. Sci., 1913, pp. 131-137, flys.* 5).—Observations were made regarding the influence of certain fertilizing agents on scab.

It appeared that very little scab lived through the winter in a loamy soil, while in soils of more open texture, as peat or sand, the spores survived. Sulphur (but not sulphates) apparently has a marked influence in reducing scab, but chlorids increase the amount of that disease.

Report of pathologist, D. H. Rose (Missouri Fruit Sta. Rpt. 1913-14, pp. 19-32, pls. 2).—A report is given of diseases of fruit trees and other plants, some of which have been subjected to definite study, while others are merely reported as having been observed.

Among the apple diseases studied are said to be a pimple canker or measles, several kinds of fruit spot, ring rot or blossom-end rot due to *Sphæropsis malorum* after frost injury, curly leaf, cankers, bitter rot, etc. The study of the pimple canker of apples has shown that it is the same as that described in Arkansas Station Bulletin 112 (E. S. R., 29, p. 649). While numerous inoculations have been made, using three different organisms obtained in cultures, no positive results have been secured. Among the fruit spots studied are the

Jonathan spot, a red lenticel spot on several varieties of yellow and green apples, and a green sunken spot on the varieties Ben Davis and Shannon. From the first two spots a species of Alternaria has been uniformly separated, while from the third several fungi have been obtained which are to be investigated further. For the control of the bitter rot the author has found four sprayings with Bordeaux mixture necessary in case of severe infection.

Studies of peach diseases have shown that both the brown rot and scab may be controlled by the use of self-boiled lime sulphur.

A study of grape diseases has shown the presence of three diseases not previously reported from the station, a bitter ripe rot due to Mclanconium fuligineum, necrosis or dead arm caused by Cryptosporella viticola, and a leaf spot due to a species of Pestalozzia.

The report concludes with an account of the cooperative work of the station with spraying, pruning, fertilization, and cultivation of fruit, principally apples, peaches, and strawberries,

Methods for controlling fungus diseases of the apple in New York State. D. Reddick (Conn. Pomol. Soc. Proc., 22 (1913), pp. 30-46).—This is a discussion of apple scab and its control, also brief mention of fruit spot. and blotch, bitter rot, rust, canker, collar rot, fire blight, Baldwin spot, and sun scald.

The cause of bitter pit: Its contributing factors, together with an investigation of susceptibility and immunity in apple varieties, D. Mcalpine (Prog. Rpt. Bitter Pit Invest. [Aust.], 2 (1912-13), pp. 224, pls. 62).—In continuation of a previous report (E. S. R., 31, p. 244), the author discusses the causes of bitter pit and those factors which contribute to its development. From experimental evidence it is concluded that temperature and humidity induce bitter pit, and it was found that if apples are stored at a temperature of from 30 to 32° F, in dry air the development of bitter pit is retarded.

Respiration in apple leaves infected with Gymnosporangium, H. S. Reed and C. H. Crabill (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 180).—The authors found that diseased leaves uniformly produce more carbon dioxid than healthy leaves, various factors influencing the process.

Some effects of the brown rot fungus upon the composition of the peach, L. A. Hawkins (Amer. Jour. Bot., 2 (1915), No. 2, pp. 71-81; Abs. in Science, n. ser., 41 (1915), No. 1048, p. 179).—The results are given of several series of experiments on the effect of the brown rot fungus on certain carbon compounds in the peach fruit.

In the experiments one-half of the peach was inoculated with a fungus while the other was kept sterile under the same moisture and temperature conditions. At the end of two or three weeks the different portions were analyzed and it was found that in the rotted portion the pentosan content was practically the same as in the sound half. The acid content was increased; the amount of alcohol-insoluble substance which reduces Fehling's solution when hydrolyzed with dilute hydrochloric acid was decreased; and the total sugar content was decreased, while the cane sugar practically disappeared.

[A banana disease in Hawaii], E. V. Wilcox (Hawaii Sta. Rpt. 1914, pp. 23, 24).—A brief account is given of a disease of banana that has been under observation in Hawaii for several years, and which has been confused with the Panama disease.

An examination of infested leaves, by a pathologist of the Hawaiian Sugar Planters' Station, showed the presence of a Fusarium, and at the border line between healthy and diseased material a bacterial organism was found. The disease has not been reproduced by inoculation, so the cause can not be definitely assigned. The most obvious symptom of the disease is the death and

decay of the terminal young leaves and the production of narrow, yellow, wrinkled leaves. The bunches of fruit are also much distorted.

Spraying with fungicides has not proved effective for the control of this disease, but if the diseased plants are cut out and destroyed by fire as soon as observed, it is held under control. The disease seems to be confined chiefly to the Chinese banana.

[Panama disease of banana] (Jour. Jamaica Agr. Soc., 18 (1914), No. 11, pp. 450-455).—This is a report, with discussion, of a special committee on Panama disease discovered in 1912 and now appearing in new places on several estates in parts of Jamaica. It is said to be spread by planting suckers from diseased plants, also probably through dissemination of spores by laborers on tools, clothing, earth from diseased roots, etc.

The disease is said to be controllable, when found in any given spot, by the destruction of all the plants in the Immediate neighborhood, and by drainage of the flood water therefrom into pits treated with lime. In Jamaica the disease has seldom reappeared after thorough treatment.

[Banana disease], S. F. Ashby (Jour. Jamaica Agr. Soc., 18 (1914), No. 11, p. 457).—This is a report by the government microbiologist on diseased banana material sent for examination from Glengoffe. Root galls are described as due to a Heterodera. A bud rot yielded two undetermined bacteria which closely resembled that causing the bud rot of coconut.

The extension of Marsonia rosæ in rose culture, Chifflot (Compt. Rend. Acad. Sci. [Paris], 159 (1914), No. 4, pp. 336-338).—Reporting observations on M. rosæ the author states that this fungus, formerly thought to be confined to the subcuticular portions of the leaves, may, in case of certain rose varieties, extend itself to deeper cell layers and to any aerial portion of the plant. The mycelium is thought to be perennial and capable of transmission through grafts.

Removal of all diseased or fallen leaves and thorough spraying with fungicides is recommended. For this purpose Burgundy or Bordeaux mixture may be employed at from 0.8 to 1 per cent strength, adding 0.05 per cent of gelatin previously dissolved in hot water to augment its spreading and adherent qualities.

Influence of the medium on the development of Lophodermium nervisequum, E. Mer. (Rev. Gén. Bot., 25 bis (1914), pp. 511-527).—Having investigated further (E. S. R., 27, p. 854) the factors in the evolution of L. nervisequum on fir, the author states that the conditions of the medium (including not only weather, etc., but also conditions internal to the host) are very influential in this connection. The fungus is thought to attack only those branches whose foliage is not in full vigor.

Improvement of living conditions and employment of copper fungicides, it is thought, may prevent serious damage from this fungus, which is not considered as necessarily very injurious.

Pyropolyporus everhartii as a wound parasite, G. N. Hoffer (*Proc. Ind. Acad. Sci., 1913, pp. 99-101, figs. 4*).—Reporting observations on *P. everhartii*, thought to be of considerable economic importance in Indiana, the author adds *Quereus alba* to the list of its hosts as given by Hedgeock (E. S. R., 27, p. 653).

ECONOMIC ZOOLOGY-ENTOMOLOGY.

The animal enemies of agricultural plants, M. NEVEU-LEMAIRE (In Parasitologie des Plantes Agricoles. Paris: J. Lamarre & Co., 1913, pp. 267-655. figs. 194).—In this work the author presents a brief discussion by orders of the

more important animal enemies of plants and includes a list of these pests under the crops attacked, and of their natural enemies.

The pocket gopher, H. B. YOCOM (Kansas Sta. Circ. 43, pp. 4).—This is a résumé of Bulletin 172, previously noted (E. S. R., 24, p. 254).

Report of the entomologist, D. T. FULLAWAY (Hawaii 8ta, Rpt. 1914, pp. 43-50).—On account of the author's detail to work with parasites of the Mediterranean fruit fly for the territorial government of Hawaii and for the Philippine government for periods totaling 8 months, but little entomological investigational work was conducted.

The report consists largely of accounts of insect pests of vegetables, particularly those affecting cabbage, turnip, radish, lettuce, etc. The three most important pests of crucifers in Hawaii, the imported cabbage worm, the cabbage webworm, and the diamond-back moth are considered at some length. The cabbage plant lice (Aphis brassica and Myzus persica) are at times of considerable importance, while the serpentine leaf miner, cutworms, and other caterpillars of general feeding habits, as well as grasshoppers and thrips, are pests of minor importance.

Fifteenth report of the state entomologist of Minnesota, F. L. WASHBURN (Rpt. State Ent. Minn., 15 (1913–14), pp. XVI+107+100, pls. 16, figs. 26).—
This report consists of papers on Useful Birds Found in Minnesota (pp. 1–19) and a Report on Inspection of Minnesota Nurseries and of Imported Nursery Stock and Ornamentals 1913–14 (pp. 20–51), by F. L. Washburn; Spraying in Minnesota (pp. 52, 53) and Some Important Tree Insects (pp. 54–56), by A. G. Ruggles; Some New Suggestions in Fly Control (pp. 57–60) and Warble Flies (pp. 61–63), by C. W. Howard; Truck Crop Insects, by W. Moore (pp. 64–68; Wireworms, by W. Williamson (pp. 69–72); Preliminary Notes on the Odonata of Southern Minnesota, by A. D. Whedon (pp. 77–103); and a complete index to volumes 1 and 2 of the popular publication known as Insect Life.

A synopsis on the Acridiide of Minnesota, by M. P. Somes (pp. 7-100), previously noted (E. S. R., 31, p. 650), is appended.

Entomologist's report, M. P. Somes (Missouri Fruit Sta. Rpt. 1913-14, pp. 4-19, pls. 2).—This report deals with the occurrence of and work with the more important enemies of orchard and small fruits for the period from September, 1913, to January, 1915.

The grape tiger moth (Apantesis arge), apparently unrecorded heretofore as of economic importance, was the source of severe loss at several points. The eggs, which were first observed June 23 on grape twigs and petioles in numbers varying from 70 to 280 each, hatched on June 27. The larvæ which are voracious feeders had all pupated by August 26 and adults emerged September 2. Arsenate of lead paste 2 lbs. to 50 gal, of water applied July 2 is said to have been a satisfactory means of control.

Jalysus spinosus, a small bug belonging to the family Berytidæ, which has never been recorded as of economic importance, is said to have been a serious enemy of the tomato in all parts of the State and even as far north as Sioux City. Iowa. The eggs deposited on tomato stems in cages on July 27 hatched August 1. The nymphs and adults feed upon the juices of the tomato by puncturing the stem, branchlets, and in some cases the fruit itself. In southern Missouri there appear to be three or more broods each year. In addition to grape it has been observed on oak, hazel brush, sumac, peach, corn, alfalfa, and horse nettle. Though a difficult pest to control by contact insecticides it was found that by spraying late in the afternoon and early in the morning while the bugs were sluggish, good results could be obtained from the use of either kerosene emulsion or blackleaf 40.

The chrysomelid beetle Orsodaena atra, another insect not previously recorded as a fruit pest, was found throughout southern Missouri in the early spring eating through the flow r buds of peach, cherry, apple, and pear to feed upon the stamens.

Twelfth annual report of the state entomologist of Montana, R. A. Cooley (Montana Sta. Bul. 102 (1914), pp. 191-208, fig. 1).—The author presents brief notes on the occurrence of the more important insect pests during 1914.

[Destructive insects in 1913] (Bd. Agr. and Fisheries [London], Ann. Rpt. Hort. Branch, 1913-14, pp. 55-77). The occurrence of and work with the large larch sawdy (Lygaronematus crichsonii), the small ermine moths (Hyponomeuta spp.), and diseases of bees are discussed at some length.

Entomological notes (Cyprus Jour, No. 35 (1914), pp. 805-807).—The notes here presented relate to injury to the grape by Eolothrips vitis; the steps to be taken in the destruction of Cecidomyia ceratonia. which causes stunted fructification of the carob, pepper, and caper; and the damage done by the cotton bollworm, the loss in some cases amounting to 50 per cent of the yield. A, vitis causes a characteristic scar or spot upon the grape and also produces a curling of the tender shoots and a stunted development of the growth of twigs, stems, and leaves.

Insect pests of some leguminous plants, Λ . RUTHERFORD (Trop.~Agr. [Ceylon], 43 (1914), No.~4,~pp.~319-323).—This article consists of miscellaneeus notes on the insect enemies of leguminous plants in Ceylon.

Pests and diseases of the coconut palm, W. W. Froggatt (Dept. Agr. N. S. Wales, Sci. Bul. 2, 3, ed., rev. and enl. (1914), pp. 63, figs. 44).—A revised and enlarged edition of the bulletin previously noted (E. S. R., 26, p. 60).

The transmission of swamp fever, J. W. Scott (Wyoming Sta. Rpt. 1914, pp. 180–188).—This is in continuation of the work by Swingle, previously noted (E. S. R., 30, p. 687). The work of the year was devoted to a study of the agents that might be concerned in the external transmission of the infection. By elimination it was concluded that the agent or agents must be bloodsucking and that only certain mosquitoes and biting flies have the broad geographical distribution characteristic of swamp fever. For the purpose of testing these insects a screened cage of 16-mesh wire, 22 ft. long by 20 ft. wide, was constructed.

The experiments, which are described in detail, have led to the conclusion that swamp fever can be, and under natural conditions probably is, transmitted by biting insects. In the investigation conducted the infection was transmitted either by the stable fly (Stomoxys calcitrans) or by certain mosquitoes, or both, the author being of the opinion that the stable fly was the agent responsible.

The control of chicken mites and lice, R. M. Sherwood (1000 Sta. Circ. 19 (1914), pp. 2).—A brief description is given of these common fowl parasites and means for their control.

Cyanid of potassium in trees, H. A. Surface (Science, n. ser., 40 (1914), No. 1041, pp. 852, 853).—Replying to an article by Sanford relating to the subject, previously noted (E. S. R., 32, p. 152), the author calls attention to observations of the use of cyanid of potassium, chlorate of potash, and sulphate of iron. Hundreds of trees treated by an agent of a company engaged in the business upon examination showed no infestation by the San José scale, while on others the scale had not been injuriously affected. A large number of the trees are said to have been killed by the treatment.

The author concludes that while some chemicals may be taken up in the trees, and may even destroy some insects, it is evident that they may be in-

jurious to the trees and should be applied with great care and only after considerable experimentation.

How to collect and preserve insects, F. E. LUTZ (Amer. Mus. Nat. Hist. Guide Leaflet 39 (1914), pp. 21. figs. 13).—This paper furnishes information for those interested in the collection and preservation of insects.

Insects injurious to forests and forest products.—Biology of the termites of the eastern United States, with preventive and remedial measures, T. E. SNYDER (U. S. Dept. Agr., Bur. Ent. Bul. 94, pt. 2 (1915), pp. V+13-85, pts. 15, figs. 11).—This account is based largely upon investigations conducted by the author during 1910 and 1911 as to the character and extent of damage to telephone and telegraph poles and mine props by wood-boring insects as described in Part 1 (E. S. R., 25, p. 51), together with additional experiments conducted during the past three years.

Termites, commonly known as white ants, are among the most destructive insects of North America to both crude and finished forest products. The species considered in this paper are *Leucotermes flavipes* and *L. virginicus*, the former widely distributed over the United States, while the recorded distribution of the latter is more limited.

The subject is dealt with under the headings of history, biological experiments, communal organization, the different castes—polymorphism, the life cycle, cannibalism, situation of the different forms in the nest, the swarm or so-called nuptial flight, the establishment of new colonies, the royal pair and other reproductive forms, dates of the swarming of Leucotermes, association with ants, termitophilous insects, parasites, summary and conclusions based on the results of the experiments, the damage to forest products, preventives, remedies, and "immune" woods, and method of obtaining photographs for the illustrations.

A bibliography is included.

"Thrips" in orchards.—A warning to fruit growers, W. B. Gurney (Agr. Gaz. N. 8. Wales, 25 (1914). No. 8, pp. 685-687).—In 1913 thrips destroyed a large percentage of the apple crop, and also attacked pear and other blossoms, causing very heavy loss to many growers. This outbreak is thought to have been the worst to take place for many years. The early flowering forms are said to escape very much damage, the late blossoming apples being those chiefly injured. Thrips tabaci is thought to be the species concerned.

Diaspis pentagona and Prospaltella berlesei in the Province of Venice at the end of 1913, A. Berlese (Redia, 9 (1913), No. 2, pp. 235–283, figs. 20).—This paper reviews at some length the progress made up to the end of 1913 in the control of the mulberry or West Indian peach scale (Aulacaspis pentagona) by P. berlesei. A previous account of the benefits resulting from the work of this parasite has been noted (E. S. R., 29, p. S54).

Aphids on grain and cantaloups, C. W. Woodworth (California Sta. Circ. 125 (1915), pp. 4, fig. 1).—A popular account of the oat and cotton aphids (Aphis arena and A. yossypii).

Two clover aphids, Edith M. Patch (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 5, pp. 431-433, figs. 3).—This paper discusses the long-beaked clover aphid (Aphis brevis) and the short-beaked clover aphid (A. bakeri), which have been rather generally confused in collections under the latter name. The range of both species extends nearly all, if not quite, across the continent.

A. brevis leaves the hawthorn, the leaves of which it causes to curl, during June and early July and returns late in the season before producing the sexual generation. Fall migrants were taken on cultivated plum (Prunus spp.) by the author, but no spring collections have as yet been made from that host. Ap-

parently the same species was collected in June and July from the twigs and terminal leaf curls of the Japan quince (Cydonia japonica). In transfer tests during 1912 A, brevis was found to accept both alsike and other clover (Trifotium spp.). Migrants placed on alsike and white clover produced uymphs that fed with apparent satisfaction on the test plants. Sweet pea (Lathyrus odoratus) vines were found to be infested by this species in August.

A. bakeri was taken from Trifolium pratense at Orono, Me., about the middle of August. It is found upon shepherd's-purse (Capsella barsa-pastoris) in the fall and early spring, but whether there is a migration between shepherd's-purse and clover has not been determined. Specimens from hawthorn in Oregon were examined, and it is reported to occur on apple (Malus spp.) in Colorado. The author made a single collection of a fall migrant on hawthorn at Orono on October 1, 1944.

Our common butterflies, F. E. LUTZ (Amer. Mus. Nat. Hist. Guide Leaflet 38 (1914), pp. 25, figs. 40).—A popular account.

Some notes on the life history and habits of Lauron vinosa, T. H. Jones (Insecutor Inscitic Menstruus, 2 (1914), No. 7, pp. 108-111).—The larva of this lepidopteran is said to cause the death of Heliotropium indicum, which occurs as a weed in and about the sugar-cane fields at Rio Piedras, P. R.

The Hessian fly, F. M. Webster (U. S. Dept. Agr., Farmers' Bul. 640 (1915), pp. 20, figs. 17).—This is a revision of Circular 70 of the Bureau of Entomology, previously noted (E. S. R., 17, p. 1089).

Life history of the Mediterranean fruit fly from the standpoint of parasite introduction, E. A. BACK and C. E. PEMBERTON (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 5, pp. 363-374, pls. 2).—The authors first describe methods for rearing fruit flies which developed during the course of their work. During warm weather nearly all puparia are formed in from one to two hours. The minimum length of the pupal stage is 6 days when the mean temperature ranges from about 76 to 79° F., but even during the warmest weather in Honolulu the larger proportion of any lot of pupe required from 9 to 11 days before yielding adults. The period may be increased to at least 19 days when the daily mean drops to about 69 to 71°. The authors have found that the fly can pass from egg to adult if kept in the dark in cold storage at 56 to 57°, and that at this temperature practically all pupe yield adults from 37 to 41 days after pupation. "Pupæ placed in cold storage in the light at a temperature varying between 58 and 62° were apparently unaffected by the cold, except that the length of the stage was increased to from 29 to 31 days for pupæ which were about three hours old when placed in cold storage. In carrying pupæ from place to place for rearing purposes a temperature of less than 56 to 60° is not advised, as great mortality occurs. Thus, from about 300 pupe 1 day old placed in cold storage at about 50° on June 2 and removed to a normal summer temperature at Honolulu on July 22, only 8 adults emerged during the period from July 24 to 26."

Well-fed Mediterranean fruit flies were kept alive in jars when fed on sweetened fruit juices for more than 5 months, although 50 per cent usually die within two months after emergence. Oviposition was found to take place in Hawaii as early as five days after emergence during very warm weather, but not for about 10 days when the temperature ranged between 68 and 72°. Records kept of females showed that during the first 18 weeks of the life of one female more than 499 eggs were deposited, at the end of which time she was in a thrifty condition. Two other females during the same period deposited 416 and 336 eggs, respectively, while a fourth female living but 80 days deposited 312 eggs. The authors point out differences in habits between the adult Mediterranean fruit fly and the adult melon fly (Bactrocera cucurbitae), the latter being far more

hardy and more irregular in habits of oviposition. Details relating to the observations reported are presented in tabular form.

Reconnoissance of fruit fly parasites, W. M. GIFFARD (Hawaii, Forester and Agr., 11 (1914), No. 11, pp. 334-337).—Investigations made in the Kona district on the island of Hawaii during October by the author and E. A. Back, of the Bureau of Entomology of this Department, show that the braconid parasites Opius humilis introduced from South Africa and Diachasma tryoni from Australia by Silvestri have become established and are increasing in numbers. It was found that the infestation of coffee berries by the fruit fly in this district during the year was at least 50 per cent less than in 1913.

Sheep magget flies, W. W. Froggatt (Apr. Gaz. V. 8, Wales, 25 (1914), No. 9, pp. 756-758, pl. 1).—This is a description of the more common sheep magget flies, accompanied by a colored plate, with the eight species described.

The parasite of the sheep magget fly (Nasonia brevicornis), W. W. Frog-Gatt (Agr. Gaz. N. 8. Wates, 25 (1914), No. 9, pp. 759-764).—This chalcidid, originally described from Illinois in 1909 (E. S. R., 23, p. 161), where it was reared from pupe of different species of Diptera and since recorded from Chile, is reported by the author to have been discovered in New South Wales and Queensland, and to be a common parasite of the puparia of the blow flies, there known as "sheep-magget flies."

In breeding experiments in which all kinds of blow flies and maggots were used it was found that the parasite showed a preference for the smooth, thin-skinned pupe of Calliphora villosa, C. occania, and C. crythrocephala, and infested the stoutly-spined pupe of C. ruffacies only when the others were unobtainable. The very noticeable decrease within a few years of the common yellow blow flies and Ophyra nigra in the Northwest during the summer months leads the author to think that these parasites first attacked the pupe of those blow flies with smooth pupe and have only recently turned their attention to the harder spiny pupe of the "hairy maggot" of C. ruffacies.

Ten generations of this parasite are said to have been produced in the course of six months from a few hundred of parasitized pupe originally collected at Brewarrina. The eggs hatch in about three days' time, seven days are required for the development of the larvæ, and about five days are passed in the pupal stage.

The eradication of the sheep tick, L. D. Swingle (Wyoming Sta. Bul. 105 (1915), pp. 27-47).—This is a report of experiments with a number of dips for controlling the sheep tick, a life-history study of which has been previously noted (E. S. R., 29, p. 756). It appears that one dipping can not invariably be depended upon to eradicate the tick, while two dippings, with an interval of 24 days during warm weather and 26 days in the spring or fall, either with coaltar products or with Cooper's Powder will absolutely destroy them. Early fall appears to be the best time for the dipping.

List of Tachinidæ from the Province of Quebec, J. D. TOTHILL (Ottawa Nat., 28 (1914), No. 9, pp. 113-116).—Forty-nine species of this family of dipterous parasites are listed as occurring in the Province of Quebec.

[The hen flea (Sarcopsylla gallinacea)], E. V. Wilcox (Hawaii Sta. Rpt. 1914, p. 24).—This pest made its appearance in Honolulu during the year and is said to be spreading rapidly. In a test of several insecticides it was found that a single application of kerosene killed about 75 per cent of the fleas. All of the fleas were killed by an application of carbolated vaselin (2 per cent carbolic acid) and by a 3 per cent solution of carbolated acid in glycerin and water. Zenoleum in a 3 per cent solution was about as effective as kerosene. The trouble is said to be so serious that poultry raisers should thoroughly spray

infested yards, and since rats may also carry these fleas an attempt should be made to eradicate them.

List of generic names and their type species in the coleopterous superfamily Scolytoidea, A. D. HOPKINS (Proc. U. S. Nat. Mus., 48 (1914), pp. 115-136).—This is the second contribution toward a monograph of the scolytoid beetles.

An alphabetical list is given of the generic names, including the author, the original reference, the type species, the author of the species, and if not monobasic the authority for the designation and the locality or country from which the type is described. No attempt is made to indicate the synonyms and no distinction is made between generic and subgeneric names, but the generic and subgeneric names in the superfamily that have been published to December 2, 1912, have been included. An alphabetical list is given of the names of type species, including the names of the authors, the names of the genera of which the species were originally described, and the names of the genera of which they are the type.

Classification of the Cryphalinæ with descriptions of new genera and species, A. D. Horkins (U. S. Dept. Agr. Rpt. 99 (1915), pp. 75, pls. 4, fig. 1).—
This is the fourth contribution toward a monograph of the scolytoid beetles, of which the first and third have been previously noted (E. S. R., 21, p. 557; 32, p. 658) and the second is noted above. The subfamily Cryphalinæ of the family Ipidæ includes a group of ambrosia beetles, also known as pin-hole borers and timber beetles, which are exceedingly detrimental to crude forest products, wine and beer casks, and other similar products; a species destructive to the tea plant in Ceylon; and many seed-infesting insects, especially those of the date palm. Numerous new species are described and genera erected.

Xyleborus compactus, a borer of tea and coffee, A. RUTHERFORD (*Trop. Agr.* [Ceylon], 42 (1914), No. 2, pp. 131, 132).—This is a report of studies of a borer, widely distributed in Ceylon, which resembles the shot-hole borer of tea (X. fornicatus), but works in a different way. It is reported to attack both coffee and tea plants, as high as 50 per cent of the plants in a tea nursery at Wattegama having been injured.

Plants other than tea from which Xyleborus fornicatus (shot-hole borer of tea) has been taken, A. RUTHERFORD (Trop. Agr. [Ceylon], 4,2 (1914), No. 4, pp. 307-309).—An annotated list of plants other than tea that are known to have been attacked by this beetle.

The Hymenoptera of the Georgetown Museum, III, IV, and V, P. CAMERON (Timehri, Brit. Guiana, 3, ser., 2 (1912), Nos. 1, pp. 207-231; 2, pp. 413-440; 3 (1913), No. 1, pp. 105-137).—Part 3 of this paper (E. S. R., 26, p. 353) deals with the marabuntas or wasps, 28 new species of social and 42 of solitary wasps being described for the first time. Part 4 deals with the fossorial Hymenoptera and part 5 presents descriptions of species belonging to the families Chalcidide, Perilampide, Eurytomidæ, Encyrtidæ, Proctotrypidæ, etc.

The mason bees, J. H. Fabre (New York: Dodd, Mead & Co., 1914, pp. VIII+315).—This is a translation of the essays on Chalicodoma spp. from the author's Souvenirs entomologiques.

Apiary work, J. B. Thompson (Guam Sta. Rpt. 1914, pp. 16, 17).—This is a brief statement of the progress of apiculture in Guam. It is stated that since the inauguration of the apiary work at the station not less than 12 parties have obtained for their own use improved movable frame hives and are now handling bees on a more or less extensive scale under greatly improved conditions, while the governor of the Island has added a course on practical bee keeping to the work of common schools.

Recent experience and progress in bee keeping in Germany, F. Gerstung (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 6, pp. 716-721).—This is a more detailed report than that previously noted (E. S. R., 30, p. 759).

The morphology, biology, and economic importance of Nosema bombi n. sp., parasitic in various humblebees (Bombus spp.), H. B. FANTHAM and Annie Porter (Ann. Trop. Med. and Par., 8 (1914), No. 3, pp. 623-638, pl. 1).—
"N. bombi n. sp. is parasitic in the alimentary canal and Malpighian tubules of various species of humble (or bumble) bees, Bombus agrorum, B. hortorum, B. latreillelus, B. lapidarius, B. sylvarum, and B. terrestris being affected. It may also pass naturally to the hive bee, Aphis mellifica and to A. florea. It is pathogenic to all the above hosts. The morphology of N. bombi resembles that of N. apis in its general outlines. . . .

"The mode of infection is contaminative by means of infected food and drink. Larvæ can become infected from the food soiled by the parental excrement in which they hatch out. N. bombi can pass from one species of humblebee to another without change of morphology or virulence. When it reaches hive bees its facies is preserved, but its pathogenic action is accelerated. . . . The dearth of humblebees due to the action of N. bombi has resulted in less red clover seed in certain districts. The possibility of the contraction of microsporidiosis of humblebees by hive bees is also not without significance.

"Preventive measures from the economic standpoint take two main forms:
(a) Destruction by burning of all dead humblebees found and of the nests of moribund bees when they are detected. (b) Prevention of the thoughtless destruction of healthy nests, more especially by children. The destruction of the diseased and preservation of the healthy humblebees are both in the interests of agriculturists."

Some observations on the life history and bionomics of the knapweed gall fly (Urophora solstitialis), J. T. Wadsworth (Ann. Appl. Biol., 1 (1914), No. 2, pp. 142-169, pls. 2, fig. 1).—A discussion of the life history and bionomics of the trypetid gall fly U. solstitialis in connection with the literature relating to it.

The anatomy and life history of Agchylostoma duodenale, II, A. Looss (Rec. Egypt Govt. School Med. Caivo, 1911, pp. 163-613, pls. 9; rev. in Jour. Econ. Biol., 7 (1912), No. 1, p. 27; Jour. Roy. Army Med. Corps, 19 (1912), No. 1, pp. 42-55, figs. 22).—Following a brief introduction the author gives a general account of the comparative anatomy, classification, and development of nematodes, with special consideration of those points which have led earlier authors into error. This is followed by a detailed account of the development, in which the egg, its shell, contents, and stage at which the eggs are laid, are dealt with, also the eggs of other nematodes, which have been, or might be mistaken for the eggs of the species treated of. The consideration of fertilized and unfertilized eggs, the embryonic development, the hatching of the embryos, etc., form a second section, and separate sections are devoted to the consideration of the conditions necessary for the development of the eggs and larvæ; the biology of the mature larvæ; modes of infection; the migration of the larvæ; the symptoms produced by the migration of the larvæ in man; and the comparative frequency and practical significance of the two modes of infection. i. e., oral and dermal.

An extensive bibliography, index to authors quoted, and a list of the genera and species referred to are included.

FOODS-HUMAN NUTRITION.

Second Congress of Alimentation, Liége, October 1–4, 1911 (2, Cong. Aliment. Liége, 1911, pl. 1, pp. 393).—In this report of the second food congress, held at Liége, October 1–4, 1911, are included a number of papers presented to the congress which relate to various subjects under food and nutrition, such as milk and dairy products, meat and meat products, fatty foods, cereal foods, beverages, condiments, physiology, etc. The following may be mentioned: Changes Undergone by Canned Meats, by G. Mayer; Quantitative Analysis of Cereals as an Index of their Bread-making Value, by R. Ledent; Pastry and Hygiene, by J. B. E. Haeffelé; Composition and Uses of Artificial Honey, by G. Romberg; The Influence of Several Different Foods upon the Digestion of Each, and upon the Extent of their Utilization, by E. Zunz; Effect of Cooking on the Digestion of Foods, by E. Zunz; and Dried Milk as Food for Infants, by Peers de Nieuwburg.

Bibliography of Belgian publications on nutrition and hygiene, A. J. J. VANDEVELDE and H. W. J. VAN BERESTEYN (Verslag, en Meded, K. Vlaam, Acad. Taal en Letterk., 1913, pp. 697-756).—A number of references are given which are listed both by authors and subjects.

Physiological bibliography (Bibliographia Physiol., 3, ser., 9 (1913), No. 2, pp. 233-399).—A number of references to English, French, German, and Italian work on general physiological problems, including respiration, digestion, and nutrition, are given.

The nutritive value of ossein and its use in the diet, E. MAURIÉ (Compt. Rend. Acad. Sci. [Paris], 159 (1914), No. 8, pp. 450-452).—The author suggests the use of dried ossein, in powdered form, of which he has used daily as much as 75 gm. added to bouillon. It is stated that the ossein is readily assimilated.

Meat poisoning and the isolation and nomenclature of meat poisoning bacteria, W. Pfeller and F. Engelhardt (Mitt. Kaiser Wilhelms Inst. Landw. Bromberg, 6 (1914), No. 4, pp. 244-260).—In an investigation of several cases of meat poisoning, attributed to bacteria of the paratyphoid and Gaertner types, a bacteriological study was made of these organisms.

The food value and toxicity of fungi, U. Selan (Rivista [Conegliano], 5. ser., 20 (1914), Nos. 21, pp. 496-500; 22, pp. 515-518).—Food values and proximate analyses are given. Practical methods for distinguishing between edible and poisonous varieties and remedial measures for fungi poisoning are discussed.

Some Colorado mushrooms, B. O. Longyear (Colorado Sta. Bul. 201 (1914), pp. 34, pl. 1, figs. 27).—Botanical and general descriptions are given of both edible and poisonous species of fungi. Popular misconceptions regarding mushrooms and toadstools are discussed and the author recommends the recognition of these plants by their botanical characters rather than by some general or uncertain rule. Directions are given for cooking and preparing mushrooms for the table.

Barley (Food and Drugs, n. ser., 2 (1914), No. 4, pp. 196-201, figs. 2).—General data are given regarding the cultivation, chemical composition, nutritive value, and uses of barley.

Milling and baking studies, A. Atkinson and B. W. Whitlock (Montana Sta. Bul. 101 (1914), pp. 176–193, figs. 23).—In the first annual report of the State Grain Laboratory of Montana the equipment is described briefly and the results are reported of chemical analyses and milling and baking tests carried out with 14 varieties of wheat, including durum and both hard and soft winter and spring wheats. The factors determined in the baking tests were the

percentage of absorption and the weight, volume, color, and texture of the loaf. It was found that the highest protein and gluten content do not necessarily give the best loaf. Red Russian and Minnesota 188 gave the best general results.

Baking tests of patent, straight, and clear flours from spring and winter wheats showed the highest grade in volume, color, and texture of the loaf from spring patent flour.

The use of sugar in bread making, A. Herzfeld (Deut. Zuckerindus., 39 (1914). No. 48, pp. 960, 961).—Bread prepared with the addition of molasses and other sirups, according to the author, proved very satisfactory. The taste was good and the crumb retained its moist condition. The use of sugar in this form is recommended as a means of increasing its consumption.

Uses of cassava, H. Caracciolo (Bul. Dept. Agr. Trinidad and Tobago, 13 (1914), No. 83, pp. 278, 279).—Notes are given on the utilization of cassava in the home.

The manufacture of cassava farine, L. A. Brunton (Bul. Dept. Agr. Trinidad and Tobago, 13 (1914), No. 83, pp. 277, 278).—The technique employed in cleaning, grading, draining, sifting, and drying the product is described.

The composition of Hawaiian fruits and nuts, Alice R. Thompson (Hawaii Sta. Rpt. 1914, pp. 62-73).—To secure information regarding their chemical composition, analyses were made of normal and fully ripe samples of a large number of fruits and nuts commonly occurring in Hawaii. Among the tropical fruits included were the mango, avocado, banana, breadfruit, Jack fruit, papaya, and guaya.

A bunch of Chinese bananas was picked while the fruit was very green and allowed to ripen in the laboratory. Analyses of the fruit were made when very green, when slightly yellow, and when entirely ripe. Papayas were analyzed on the day they were picked from the tree and samples of the fruit were examined in several stages of ripeness, ranging from fruit which was immature and undersized to that fully ripe.

During the ripening process of the banana it was found that the total solids decreased slightly. "The insoluble solids are almost as high as the total solids in the green banana, but decrease very rapidly on ripening, and in the ripe fruit amount to less than 3 per cent. The ash is high throughout and does not change appreciably. The acid content is but a few tenths of 1 per cent and appears to reach its maximum when the fruit is half ripe, after which it decreases. The protein is fairly high and remains constant," During the ripening of the banana the starch was found to be transformed into sugar. "When green, the starch is exceedingly high, amounting to about 20 per cent, while the sucrose and reducing sugars amount to a few tenths of a per cent. At the half-ripe stage the sugars have increased several per cent and in about the same proportion that the starch has decreased. In the fully ripened stage the sugars have increased greatly and the starch has almost disappeared. The hydrolyzable carbohydrates, other than starch or sucrose, are small in amounts."

In the case of the papaya the total solids were found to be low throughout the ripening process and increased as the fruit ripened. "The insoluble solids are about 3 per cent in the green fruit and decrease to about 1 per cent in the ripe fruit. The ash, acid, and protein occur in small quantities and are quite constant. The fruit contains not more than a trace of sucrose. The reducing sugars in the green fruit, however, amount to over 2 per cent, but increase rapidly as the fruit increases in size and approaches ripeness. The hydrolyzable carbohydrates are almost nil, and fat, fiber, and undetermined matter

occur only in small amounts. It is logical to conclude, therefore, that, as the fruit when green has no store of carbohydrates upon which to draw, it must obtain its sugars by translocation from the trunk of the trees,

Evaporated apples, A. McGnl. (Lab. Inland Rev. Dept. Canada But. 293 (1914), pp. 25).—An examination of 184 samples of evaporated apples, purchased in Canada, for moisture, quality, soundness, and cleanliness is reported. Of these, 147 samples were regarded satisfactory as containing not more than 27 per cent of water and being fairly sound and clean. Full analytical data are given, together with definitions and recommendations for standards.

Iron in tomatoes, C. A. BRAUTLECHT and G. CRAWFORD (Jour. Indus. and Engin. Chem., 6 (1914), No. 12, pp. 1001, 1002).—The authors report analyses of tomatoes for water, ash, and iron. The iron content of the tomatoes, calculated from the iron in the ash, averaged 0.023 per cent.

The influence of glucose on the cooking temperatures of candy sirups, Λ_{MY} Daniels and Martia A. Troxell (Jour. Home Econ., 6 (1914), No. 5, pp. 457-460).—Experimental data reported led to the conclusion that the temperatures usually given for candy cookery must be revised, as they are generally intended for candies in which cane sugar is the principal constituent. When glucose is used in significant quantity lower temperatures give the desired results. A table is given showing temperatures for typical caudies in which glucose is used.

The influence of glucose on the cooking temperatures of candy sirups, AMY DANIELS (Jour. Home Econ., 6 (1914), No. 5, pp. 482-484, fig. 1).—Methods of determining the temperature of cane sugar alone and cane sugar with glucose are given. See also the above.

Strained honey, A. McGill (Lab. Inland Rev. Dept. Canada Bul. 289 (1914), pp. 27).—Definitions of honey are given and the results reported of the analysis of 194 samples purchased chiefly as strained honey. One hundred fifty-nine of these samples met the requirements of existing standards.

Olive oil and salad oil, A. McGill (Lab. Inland Rev. Dept. Canada Bul. 294 (1914). pp. 15).—This bulletin is a report of the analysis of 114 samples of edible oil sold as salad oil or olive oil, of which 85 were found to be genuine olive oil and 29 to consist entirely or in part of cottonseed oil.

The rancidity of olive oil and the oxidation of oleic acid in the presence of solar light, F. Canzoneri and G. Bianchini (Ann. Chim. Appl. [Rome], 1 (1914), No. 1-2, pp. 24-32).—This paper presents analytical data bearing on the chemical constitution of fatty acids.

Coffee and coffee substitutes, A. McGill (Lab. Inland Rev. Dept. Canada Bul. 290 (1914), pp. 37).—The results are given of the inspection and analysis of 339 samples purchased as coffee or coffee substitutes. Of these, 199 samples were found to be genuine. The remainder consisted entirely or in part of chicory and roasted cereals.

Egg albumin in baking powder, H. L. Jackson (Jour. Indus. and Engin. Chem., 6 (1914). No. 12, pp. 998–1001).—This paper summarizes the results of three series of comparative baking tests in which baking powders with and without egg albumin were used. This work, in the opinion of the author, does not show any usefulness of egg albumin in baking powder when bakings are carried out under normal conditions, "and especially in the very small quantity usually present, i. e., from 0.1 to 0.2 of 1 per cent. When the temperature of the oven is too low for baking biscuits properly, egg albumin seems to aid in producing a better biscuit. When the dough is allowed to stand several hours before baking a much better biscuit is produced by the powder to which egg albumin has been added."

[Food and drug analysis], edited and compiled by R. E. STALLINGS (Mo. Bul. Ga. Dept. Agr., 1 [1914], No. 7, pp. 28).—This report contains the results of the analysis of a large number of miscellaneous food samples and drugs.

[Preliminary report of dairy and food commissioner], J. Foust (*Penn. Dept. Agr., Mo. Bul. Dairy and Food Div., 12 (1914), No. 5-6, pp. 133).*—The work carried on under the state food and drug laws during the year ended December 31, 1913, is briefly reviewed and some general data regarding food inspection and analysis are given.

[Food inspection and analysis], J. Foust et al. (Penn. Depl. Agr. Bul. 247 (1914), pp. 82).—This bulletin contains hints regarding the care of eggs on the farm, reports of licenses issued for the sale of eleomargarine, the results of an examination of a large number of miscellaneous food products, and a statement of the prosecutions brought under the state food and drug law.

[Food and drug inspection and analysis], E. F. Ladd and Alma K. Johnson (North Dakota Sta. Spec. Bul., 3 (1915), No. 15, pp. 249-264).—The bulk of this bulletin consists of a further report, by T. Sanderson, on the study of the variation of the weight of a 50-lb, sack of flour during storage (E. S. R., 30, p. 667), from which the following conclusions are drawn:

"The flour with about 11 per cent moisture will vary less in weight than if the moisture be more or less. . . .

"The normal moisture content of flour in this climate seems to be about 11 per cent. . . . The normal moisture content of wheat in this climate seems to be about 13 per cent. . . .

"Flour made from wheat with normal moisture 13 per cent with not to exceed 2 per cent added moisture in tempering will produce a flour with moisture content of about 11 per cent that will not vary in storage more than 2 per cent, and the variation is as liable to be above as below the original weight, owing to atmospheric conditions. . . .

"Ordinarily wheat with moisture content of between 14 and 15 per cent moisture is in prime condition to mill."

General and analytical data are also given regarding a number of food products and drugs.

Housewives retail market prices, edited by P. Q. Foy (Housewives Retail Market Prices, 1 (1914), Nos. 1-40, pp. [8] each; 41, pp. [10]).—This summary of data regarding retail market prices is published under the direction of Mrs. J. Heath, national president of the Housewives League.

The commercial food container, Mary Dudderidge (Housewires League Mag., 4 (1914), No. 4, pp. 11-14, figs. 8).—Data are given in this article regarding the loss of weight by absorption from foods in paper, wood, or wood pulp containers. The weight of the material absorbed by the dish varied from about 6 gm, to as high as approximately 52 gm. The greatest absorption was noted in the wood pulp container and the smallest in the wood container.

Nickel cooking utensils, M. Vuk (Ztschv. Untersuch. Nahr. u. Genussmtl., 28 (1914), No. 2, pp. 103, 104; abs. in Chem. Zentbl., 1914, II. No. 13, p. 844).—The solubility of different kinds of nickel was tested by exposing 16,800 sq. mm. of surface to the action of 700 cc. of 5 per cent acetic acid for $2\frac{1}{2}$ hours. The amount of dissolved nickel varied from 16 to 65 mg. Rolled nickel was less soluble than the cast, electrolytic, or drawn nickel.

Chinese-Japanese cook book, Sara Bosse and Onoto Watanna (Chicago: Rand, McNally & Co., 1914, pp. 120).—Recipes are given for the preparation of a number of Chinese and Japanese dishes.

The vitamins and subjective factors in eating, W. Sternberg (Arch. Verdauungskrank., 20 (1914), No. 2, pp. 200-209; abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 21, p. 1696).—The author emphasizes the importance to the diet

of the flavors of foods and believes that much of what is being called vitamins is included in flavor. In his opinion the senses of smell and taste are more sensitive to chemical changes than are chemical tests. Warmed-over dishes are less appetizing than fresh dishes because they have undergone some chemical change. Loss of appetite, nauser, and some dietary deficiency disease may result from the lack of relish of food, and the author emphasizes the importance of the preparation of food which will appeal to the senses of sight, smell, and taste.

Flavors and vitamins (Jour. Amer. Med. Assoc., 63 (1914), No. 26, p. 2296).— The investigations of a number of authors are here summarized, all of which emphasize the importance in the diet of flavors, spices, and the preparation of food in such a way that it will appeal to the esthetic sense.

The influence of a diet poor in calcium upon the composition of growing bones, S. Weiser (*Biochem. Ztschr., 66* (1914), No. 1-3, pp. 95-114, figs. 3).—Previously noted from another source (E. S. R., 32, p. 465).

Contribution to the metabolism of lecithin and cholesterin with reference to the presence in the urine of trimethylamin, A. PATTA (Arch. Farmacol. Sper. e Sci. Afr., 18 (1914), Nos. 7, pp. 284-288; 8, pp. 289-298).—From a series of experiments with various laboratory animals (dogs and rabbits), the results of which are presented here in detail, the author draws the general conclusion that the presence of trimethylamin in the nrine is not, as generally believed, an indication of the metabolism of lecithin, either that obtained from the food or from the decomposition of body fat.

Metabolism of creatin and creatinin under normal conditions and as the result of suppressing the hepatic circulation, V. Scaffill (Arch. Ital. Biol., 61 (1914), No. 2, pp. 153-168).—The experimental ingestion of creatin and creatinin by laboratory animals (dog and duck) gave evidence that the liver is not a necessary organ for the metabolism of creatin and creatinin.

The presence of creatinin in the muscles and the behavior of creatin during fatigue, V. Scaffid (Arch. Ital. Biol., 61 (1914), No. 2, pp. 168-176).—Experiments with laboratory animals (frogs and dogs) are reported from which the author draws the following conclusions:

In the muscle of the animals studied, and probably in muscular tissue in general, pre-formed creatinin does not exist. Creatinin is not found in the muscles of the frog as a result of fatigue. It is probable that creatinin is destroyed as fast as formed in muscular tissue. As the result of muscular fatigue creatin undergoes no marked modifications. It is difficult to determine to what extent creatin is consumed and rebuilt from the protein decomposition products in the individual muscle.

Gastro-intestinal studies.—IV, Direct evidence of the secretion of a gastric juice of constant acid concentration by the human subject, M. E. Rehfuss and P. B. Hawk (Jour. Amer. Med. Assoc., 63 (1914), No. 24, pp. 2088–2092, figs. 7).—The results of experiments with both normal and pathological individuals indicated the secretion by the human stomach of a gastric juice which has a constant acidity.

The elimination of water under different conditions of normal respiration, A. Azzı (Arch. Ital. Biol., 61 (1914), No. 2, pp. 203-216, figs. 6).—By means of experiments with a respiration apparatus the relation existing between the elimination of water in expired air and feeding and bathing was studied. In part the following conclusions were drawn:

The kind of food has no influence upon the quantity of water in expired air. The ingestion of food, however, has a variable effect. The quantity of water eliminated in expired air increases or decreases according as a sensation of heat or cold is experienced after ingestion of food. The water content of the

expired air was increased by a warm bath and decreased by a cold bath. These experiments tend to show that the quantity of water in expired air is regulated by the vaso-motor nerve system.

Energy metabolism under conditions of muscular activity.—I, Walking experiments on a horizontal plane, E. Brezina and H. Reichel (Biochem, Ztschr., 63 (1914), No. 2-3, pp. 170-183, figs. 5).—Results are reported of experiments in which was studied the effect upon the total energy metabolism of varying the load carried and the rate of walking on a horizontal plane. A mathematical discussion of the results is also given and mathematical expressions formulated which express the relationship between the rate of walking and the weight of the load upon metabolism.

Energy metabolism during marching.—II, Walking experiment with an inclined plane, E. Brezina and W. Kolmer (Biochem. Ztschr., 65 (1914), No. 1-2, pp. 16-34, fig. 1).—Continuing previous work (E. S. R., 26, p. 872), the authors report the results of a large number of treadmill experiments in which the respiratory observations were made by means of a modified respiration apparatus. By varying the angle of inclination and the actual amount of work done, an attempt was made to determine the relationship between total work, in terms of calories, and the respiratory quotient. A gradual increase in the respiratory quotient was found to coincide with the increase in calories.

Energy metabolism in marching.—III, The laws of walking up an inclined plane, E. Brezina and H. Reichel (Biochem. Ztschr., 65 (1914), No. 1-2, pp. 35-70, figs. 8).—From the experimental data presented in the above article, a mathematical expression is derived for determining the total work done per meter of distance covered and per kilogram of body weight.

Studies of the blood after muscular work, O. Cohnhem (Zentbl. Physiol., 28 (1914), No. 12, p. 747).—After hill climbing and cycling the hemoglobin content of the blood decreased while the serum concentration increased. Perspiration alone without muscular work led to a higher hemoglobin and serum concentration.

On the action of temperature and humidity on the organism, F. S. Lee and E. L. Scott (*Proc. Soc. Expt. Biol. and Med., 12 (1914), No. 1, pp. 10-12).*—Experiments are reported in which laboratory animals (cats) were confined in a chamber and supplied with moving air at various temperatures and conditions of humidity.

"Under the influence of the high temperature and the high humidity the total amount of work which the muscles are capable of doing before exhaustion sets in is markedly diminished; and the total period of working power is shortened, except in the case of the diaphragm.

."The observations show that the bodily temperature of the animals rises in the atmosphere of high temperature and high humidity."

The qualitative relation between temperature and standard metabolism in animals, A. Kroch (Internat. Ztschr. Phys. Chem. Biol., 1 (1914), No. 5-6, pp. 491-508, figs. 5).—Experiments were carried out with laboratory animals (frogs and dogs) in which the oxygen consumption was used as an index of metabolism. Experimental technique and apparatus used are described in detail and extended experimental data are reported, which may be briefly summarized, in part, as follows:

In studying the effect of temperature upon metabolism a distinction must be made between the influence upon the central nervous system and the influence upon the reaction velocity of the metabolic processes in the tissues themselves. According to the author, when animals are studied under standard conditions—all nervous influences being abolished—the influence of temperature on the metabolism of an animal is regular and constant and can be expressed in a definite curve.

A micro-respiration apparatus correction, A. Krogn (Biochem, Ztschr., 66 (1914), No. 6, p. 512).—Formulas and values given in a previous article (E. S. R., 32, p. 67) are corrected.

ANIMAL PRODUCTION.

Pattern development in mammals and birds, G. M. Allen (Amer. Nat., 48 (1914), Nos. 571, pp. 385-412; 572, pp. 467-484; 573, pp. 550-566, figs. 62).—The author summarizes the principal points of this paper as follows:

"In mammals and birds that normally are completely pigmented there are certain definite points of the body from which as centers the tendency to develop pigment in the epidermal structures may become less and less. Outward from each of these centers pigment formation spreads to include very definite areas which in wholly pigmented animals overlap slightly at their borders or are at least contiguous.

"A reduction in the area covered by any of these primary patches results in a white mark at the line of junction of two contiguous color patches, where no pigment is produced. These white marks between the primary patches are spoken of as primary breaks.

"Through a study of the breaks in pied individuals of domesticated species of mammals and birds the boundaries of the primary patches have been determined. These are homologous in the two groups and subject to a certain amount of variation in different types. They are: A median crown patch, unpaired, and five paired patches on the opposite sides of the body, which are named from the general areas they cover, the ear, neck, shoulder, side, and rump patches. Their limits are more precisely defined under the different species treated.

"These patches are physiologically independent of each other and may be differently colored in the same individual.

"Pied patterns among many wild species have been brought about through the areal reduction of these pigment patches in a definite way, so that the white markings resulting as breaks between the reduced patches have become fixed and form a permanent part of the normal pattern.

"In several wild species this development of white markings is shown to be even now taking place, but the amount of pigment reduction is still fluctuating so that the white markings vary much in extent with different individuals.

"The development of such white markings takes place probably by little and little, so that the departure from type is not so great as to arouse antagonism against the varying individual on the part of others of its species. Also, the gradualness of the change allows the species to become accommodated to any disadvantage that might concomitantly arise.

"The converse of this centripetal style of pigmentation is present in many species, and results in pigmentation (commonly black) at the extremities or along lines where primary breaks occur in the centripetal form, namely, at the tip of the nose, ears, tip of the tail, or the toes; possibly the black dorsal stripe is due also to centrifugal pigmentation. Patterns may develop, as in certain antelopes, by a white break between patches of the two types."

Fitting logarithmic curves by the method of moments, J. R. MINER (U.S. Dept. Agr., Jour. Agr., Research, 3 (1915), No. 5, pp. 411-423).—In this paper, which includes an introductory statement by R. Pearl on the use of logarithmic curves in biological and agricultural investigations, the author attempts to im-

prove on the present method of fitting logarithmic curves by the least-squares method, by bringing this class of curves into the general system of curve fitting worked out by Pearson and known as the "method of moments." The method is worked out on the assumption that "if we equate the area and moments of a theoretical curve to the area and moments of a series of observations we shall get a reasonable fit of the curve to the observations."

A bibliography of 23 references is included.

[Animal husbandry], L. B. Barrer and J. B. Thompson (Guam Sta. Rpt. 1914, pp. 7, 8, 18-22, 25-27, pls. 3).—It is stated that the mating of a pen of single-comb Brown Leghorn hens with a native black-fleshed cock resulted in nine pullets which had dark green legs and black flesh, resembling in these features the male parent, and the remaining nine had dark green legs resembling the male parent, with white skin and flesh of a normal color resembling more closely that of the Brown Leghorn. From 25 cockerels out of the same breeding pen all had white skin and flesh resembling that of the Brown Leghorn, 20 had white legs, one had one white leg and one of a dark greenish hue, and the remaining two resembled each other in having one white leg with a black patch on the other leg. In this work a strong tendency is shown for the color characteristics to be transmitted by the parents to the progeny of the opposite sex.

In horse breeding experiments it has been demonstrated that foals from native mares and an imported stallion inherit size and quality from their superior sire, while they seem to retain in a full measure the hardiness and vitality of their native dams. Successful crossbreeding experiments with native hogs and imported Berkshires are reported.

It is stated that goats of an inferior and degenerate type which were probably introduced from Mexico are now bred on the Island. These have been occasionally crossed with a milch type, and the superiority of this cross over the native animal is well marked. It is stated that goats are reasonably hardy and free from disease in Guam, and a number of conditions exist which would indicate the adaptability of the milch goat, both in relation to the country and to the people.

The station flock of Plymouth Rocks and Brown Leghorns shows a tendency toward loss of vigor thought to result from inbreeding. Hens obtained from crossing either of the introduced breeds on the native fowl are reported to be better layers than the latter and with the hardiness of that parent not greatly reduced. In experiments with Brown Leghorn chickens, ordinary natives, native black meat fowls, and a cross between the latter and the Brown Leghorn, it was found that other things being equal all are equally susceptible to chicken pox.

Inoculation of ensiled roots with germ culture, Zscheye (Ztschr. Ver. Deut. Zuckerindus., No. 703 (1914), II, pp. 668-671).—Successful experiments are reported in inoculating ensiled roots with a lactic acid bacteria culture, resulting in a lowering of the injurious acids, acetic and butyric, as well as the ammonium nitrogen, the fermentation product of the protein material. The optimum temperature for growth of these bacteria appears to be about 35° C. The inoculated silage was of a clear color, with a clean sour smell, and in no case showed indications of spoiling, while the uninoculated silage was darker in color, showed indications of molding, and a decayed smell. In the inoculated silage there was a 24 per cent loss in the silage mass, in the uninoculated, 32 per cent.

Feeding of sugar-containing feed materials, Zuntz (Ztschr. Ver. Deut. Zuckerindus., No. 701 (1914), II, pp. 485-498).—These were respiration experiments with ruminants, in which straw, molasses, turf molasses, and sugar

beets were fed in different proportions and the energy balance estimated. Also a comparison was made of the energy value of dried turnip tops and of ensiled turnip tops in which had been introduced a lactic acid culture, in which a greater amount of combustible gases developed in the body of the animals fed the ensiled product than the dried, the protein retention was greater with the dried product than with the ensiled, but the fat ontake was greater with the ensiled product. The practical results of these experiments are summarized as follows:

The carbohydrates of molasses have a higher nutritive value for horses and swine than for ruminants, being highly usable by them. The degree of fermentation of the molasses is such that one should not feed much protein-rich feed, but such as is fed should be supplemented with a roughage feed. The organic acids of the feeds have a heat value. Reduction of the stomach fermentation with the feeding of acid or ensiled materials is doubtful.

New inquiries concerning the feeding of sugar-containing feed stuffs, ZUNTZ (ZIschr. Ver. Deut. Zuckerindus., No. 703 (1914), II. pp. 643-668).—In this article the author reviews the work presented in the above experiments, showing wherein sugar-containing feeds, such as molasses and sugar beets, are an insufficient feed in themselves, giving rise to fermentation within the body and necessitating supplementing with straw, hay, and other roughage.

Calf- and pig-feeding experiments with whole milk and corrected skim milk, O. Wellmann (Landw. Jahrb., 46 (1914), No. 4, pp. 499-626).—In these experiments one calf and eight pigs ranging in age from four to twelve weeks were fed at different times on whole milk, skim milk to which diafarin (a malt extract preparation) had been added, skim milk to which a meal starch had been added, and homogenized milk. The coefficients of digestibility for the various rations were as follows:

| Coefficients of | i diaestitilitu | with milks and | rarious summements. |
|-----------------|-----------------|----------------|---------------------|
|-----------------|-----------------|----------------|---------------------|

| Kind of animal. | Kind of ration. | Dry matter. | Protein. | Fat. | Nitro- gen-free extract. | Ash. | Energy. |
|-----------------|--|--------------------------------------|--------------------------------------|-----------------------------|--------------------------------|-------------------------|--------------------------------------|
| Calf Pigs | | Per cent. 95.00 81.76 95.47 | Per cent. 95.70 75.38 94.35 | Per cent. 95.84 88.57 | | Per cent. 80, 03 | Per cent. 94.92 78.33 95.71 |
| Pigs | Diafarin+2.5 per cent fat skim milk | 97.49 96.60 97.27 | 97.34 95.21 97.75 | 97.56 98. 97.41 | 98.17 39 96.97 | 89.74 82.63 89.11 | 97.08 96.23 97.12 |

The daily increase in weight ranged between 2.5 and 3.1 kg. per 100 kg. live weight, the daily gain increasing with advancing age. There was required per kilogram of gain from 1.2 to 1.8 kg. of milk dry matter, 1.1 to 1.7 kg. digestible organic matter, 52 to 70 gm. digestible ash, 259 to 439 gm. digestible protein, 1.1 to 1.9 kg. starch value, and 5,000 to 9.000 available calories.

Steer feeding experiments (Jahresber, Kaiser Wilhelms Inst. Landw. Bromberg, 1913, pp. 18, 19).—Two lots of 17 head of steers each were fed daily during 5½ months, 1.7 kg. digestible protein and 12 kg. starch value per 1,000 kg. live weight. Both lots were fed hay, potatoes, beets, barley meal, rape seed, rye bran, and cotton-seed meal, but lot 1 received the potatoes, beets, and rye bran in the morning ration and the remainder at night, while lot 2 received the entire feed both morning and night.

Lot 1 made an average daily gain of 0.691 kg. per head, and lot 2, 0.735 kg. On continuing this experiment for another 4 weeks, except that the steers re-

ceived 13 kg, starch value per 1.000 kg, five weight, lot 1 made an average daily gain of 0.767 kg, per head, and lot 2, 0.777 kg,

Alfalfa silage for fattening steers, G. H. True, F. W. Woll, and V. F. Doleini (California Sta, Circ. 124 (1915), pp. 4).—With a view to determining the feeding value of silage made from first cutting alfalfa composed of at least half foxtail and weeds, 107–3- and 4-year-old native range steers weighing approximately 970 lbs. each were fed 46 days a daily ration of 10.6 lbs. alfalfa hay, 20.2 lbs. silage, and 8.4 lbs. rolled barley. They made an average daily gain of 1.53 lbs. per head, requiring per pound of gain 6.9 lbs. hay, 13.1 lbs. silage, and 5.4 lbs. barley.

The alfalfa was put into the silo about May 1 and feeding was begun in July. "The silage as fed out was well made, of a dark brown color, and of slightly acidulated, aromatic flavor. That in the lower part of the silo was more moist than that in the upper part and was apparently relished best by the steers. While most of the silage was not taken with particular relish, it was always eaten up clean, with the exception of a few days during the middle of July when a layer of partially spoiled silage was reached, at a point where the filling of the silo had been interrupted for a couple of days. The foxtail heads, which would have caused great trouble in feeding the alfalfa as hay, were eaten before having a chance to dry out."

The chemical composition of the alfalfa silage was found to be moisture 76, protein 3.4, fat 0.34, hitrogen-free extract 11.72, fiber 5.56, and ash 2.98 per cent, with 0.4 per cent of volatile acids and 0.91 per cent of fixed acids.

An examination of the carcasses after slaughter showed accumulations of foxtail in the mouths of practically all the steers, which emphasizes the necessity for cutting the alfalfa for silage before the foxtail beards become hard.

Prickly-pear experiments, E. W. Horn (Dept. Agr. Bombay Bul. 58 (1913), pp. 11. pls. 10).—Six bullocks in exceptionally poor condition were fed the common variety of prickly pear found in Bombay, from which the spines had been removed by burning and which had been cut into small pieces. About 6 lbs. of cotton seed per 100 lbs. of pear was included in the ration to make it sufficiently untritious. Four of the bullocks took to the pear readily, while some difficulty was experienced with the remainder.

The pear feeding appeared to affect the excrement, making the feces of a slatish color and rather liquid, though at no time was there a tendency to scour. The urine was somewhat excessive in quantity but appeared quite normal in quality. The bullocks after a short time steadily gained in weight until a maximum was reached, after which the weights were practically constant. The avérage quantity of pear consumed was 32 lbs. per head per day, or about 72 lbs. per 1,000 lbs. live weight, varying as the pear contained more or less moisture. Assuming the coefficient of digestibility to be 66 per cent it is estimated that this allowance gave a maintenance ration, being only deficient 0.58 lb. of carbohydrate according to Haecker's standard. It is stated that as the weights of the animals increased their appearance improved, their coats becoming smooth and glossy, their eyes bright, and their health and general appearance excellent.

Very little water was needed by the bullocks while on the pear feed, although with the addition of 2 oz. of salt they drank a normal quantity.

Feeding tests with cows and buffaloes in milk were inconclusive. The composition of the pear during the dry season is given as follows: Moisture 79.32 per cent, protein 0.68, fat 0.78, carbohydrates 11.61, fiber 2.48, and ash 5.13; during the wet season, 92.65, 0.31, 0.22, 4.37, 0.85, and 1.6, respectively.

It is concluded that the pear may be used as an efficient and economical feed for cattle during periods of drought and feed shortage.

Feeding experiments with ensiled and dried beet pulp, O. Moser (Monatsh. Landw., 7 (1914), No. 7, pp. 153-158).—Oxen fed for from 174 to 200 days on beet pulp, dried and ensiled, together with hay and grain, showed a daily gain of 1.04 kg, per head on the ensiled product, 0.83 lb, gain where the ensiled and dried material was fed half and half, and 0.76 lb, gain on the dried product.

[Digestibility of Wyoming-grown hays], F. H. HILYNER (Wyoming Sta. Rpt. 1914, p. 147).—In experiments to determine the digestibility of pure native hays the following coefficients were obtained with sheep:

Digestion coefficients of Wyoming-grown lays fed to sleep.

| Kind of bay. | Dry matter. | Organie matter. | Protein. | Ether extract. | Nitro- gen-free extract. | Crude fiber. |

Uses of screenings, J. R. Dymond (Ann. Rpt. Ontario Agr. and Expt. Union, 35 (1913), pp. 64-66).—It is stated that screenings are used in large quantities for the winter feeding of sheep, the sheep being taken from the range and fed for about 30 days. At first they are given only hay, then a small quantity (½ lb. per day) of light, chaffy screenings is added. Gradually the quantity is increased until in about a week or 10 days, the sheep have access to the "self feeders" from which they eat all the screenings they care for (about 2 lbs. per day). At the same time the proportion of chaff in the screenings is decreased and the proportion of grain increased. Gradually the screenings are replaced with corn.

On the screenings the sheep usually gain from 12 to 15 lbs, during the first 30 days, after that less rapidly. It is stated that 50,000 sheep will eat about 2 cars of screenings and a car of corn per day. Seed-house screenings and screenings containing a large proportion of broken flax are avoided.

Another use that is made of elevator screenings is in the manufacture of mixed feeds, chiefly molasses feeds.

Report of the wool specialist, J. A. Hill (Wyoming Stal Rpt. 1914, pp. 162-165).—It is reported that "the results of an experiment in which 20 wethers were exchanged, ten natives of Ohio to Wyoming and ten natives of Wyoming to Ohio, show that a given sheep is likely to produce at least as much wool per year in Wyoming as in Ohio.

"The results of a 3-year experiment in which 30 Rambouillet wethers were divided into three lots of ten each and fed so as to test the effect on the wool production of the feeding without change for a year, respectively, of a wide, medium, and narrow ration, showed that the narrow ration tended to give greater wool production than either the medium or the wide." The rations were made up as follows for a lot of ten sheep: Wide, native hay 36 lbs.; medium, native hay 30 lbs., and oil cake 3 lbs.; narrow, native hay 20 lbs. and oil cake 8 lbs.

It was found from fiber tests made of the several samples that "the widemedium-narrow ration experiment shows no decided advantage in strength of wool grown during the feeding of any one of the three rations. The WyomingOhio exchange experiment shows no apparent advantage in strength for wool grown in either State."

The policy in respect to the sheep industry, T. R. Arkell (Agr. Gaz. Canada, t. (1914). No. 7, pp. 546-549, figs. 3).—It is stated that the methods of assisting sheep raisers used by the live-stock branch of the Canadian Department of Agriculture are "(1) the loaning of pure-bred sires to associations of farmers living in districts where it is difficult to obtain first-class animals or where their financial status is such that they can not afford to pay the necessary purchase price. (2) provision of the services of expert wool graders to classify and prepare in a marketable condition the wool of mutual organizations of sheep raisers. (3) prosecution of instructional and practical demonstrations by experts of the branch in the various phases of sheep husbandry, with special stress upon the most effective methods of caring for wool, which are supplemented by an exhibit containing samples of many types of wool raised in this and other countries, together with their products of manufacture."

A table is given showing the correlation of American, British, and Canadian grades of wool and their distinctive terms. There is also included a complete classification of Canadian wool.

The Maryland hog (Maryland Sta. But. 185 (1914), pp. 58. figs. 27).—This includes a discussion by C. L. Opperman of the status of the swine industry in Maryland, and of methods of housing, feeding, care, and management of hogs and the curing of pork, and a description of the various types and breeds by R. H. Ruffner.

Fattening and improving the hog, N. P. Escobar (Estac. Agr. Expt. Ciudad Juárcz, Chihuahua, Bol. 43 (1913), pp. 41, pls. 7).—This is a general bulletin treating of the different breeds of hogs and their adaptability to Mexican conditions, together with a discussion of methods of fattening and of butchering.

Stallion enrollment.—II, Stallion service liens and sale of bred mares, D. O. THOMPSON (Indiana Sta. Circ. 45 (1914), pp. 4, fig. 1).—This circular gives the text of the sections of the Indiana stallion enrollment law relating to stallion service liens and the sale of mares and foals, with a brief discussion of them.

Stallion enrollment.—III, Report of stallion enrollment work to date of October 31, 1914, with lists of stallions and jacks enrolled and a brief study of some phases of the stallion and jack situation in Indiana, D. O. Thompson (Indiana Sta. Circ. 46 (1914), pp. 355, figs. 19).—This circular gives the text of the Indiana law relating to the enrollment of stallions and jacks kept for public service; a report on work under the law; and lists showing the distribution of stallions and jacks by counties.

Stallion enrollment.—III, Renewals for 1915, D. O. Thompson (Indiana Sta. Circ. 47 (1914), pp. 4).—This circular explains the methods for veterinary examination of public service stallions and the renewal of enrollment.

Which stallion and why? (Kansas Sta. Circ. 42, pp. 4).—This circular is intended as a stimulus to the raising of better horses in Kansas. It discusses the importance of the use of a superior stallion during the breeding season and gives a list of registered stallions.

Relation of simultaneous ovulation to the production of double-yolked eggs, Maynie R. Curtis (*U. S. Dept. Agr., Jour. Agr. Research, 3* (1915), No. 5, pp. 375-385, pls. 7).—This is a continuation of work previously noted (E. S. R., 31, p. 170). The author summarizes her observations as follows:

"Double-yolked eggs with normal separate yolks may have all the egg envelopes common to the two yolks, or they may have some separate and some common envelopes. They may be classified with reasonable accuracy into three groups:

(1) Double-yolked eggs having the entire set of egg envelopes common to the two yolks; (2) double-yolked eggs having separate chalaziferous layers but all or part of the thick albumin common to the two yolks; (3) double-yolked eggs in which the yolks have entirely separate thick albumin envelopes but a common egg membrane and shell.

"Of the eggs studied 16.03 per cent belonged to type 1, 70.99 per cent to type 2, and 12.98 per cent to type 3. A large series of double-yolked eggs show all gradations within and between these groups. The most probable interpretation of this phenomenon is that the two components unite at any level of the oviduct from the funnel mouth to the isthmus ring. The conclusion that the union of the component eggs occurs indiscriminately at all levels of the oviduct is strongly supported by the fact that the percentage of eggs of each type is closely proportional to the percentage of the portion of the duct in which the union of two eggs would give double-yolked eggs of that type.

"In 36,44 per cent of the double-yolked eggs the ovulations which furnished the two yolks must have been separated by an abnormally short interval, since a normal egg had been laid on the preceding day. An examination of the egg structure, however, shows that the two yolks have passed the entire length of the duct together in only 16,28 per cent of the cases in which the ovulations are known to have been usually rapid. While a heightened rate of fecundity may result in the production of an egg of any of the three types, 68,75 per cent of the eggs of type 3 are single eggs. It seems probable that many of them have resulted from the delay of the first egg in the oviduct. The ovary of each pullet which had just laid a double-yolked egg as her first egg contained two normal separate follicles which had separate blood supplies. In these cases, however, the doubling of the egg had occurred near the end of the albumin-secreting region.

"In a case in which there was evidence from the structure of the egg that the two yolks had passed the entire length of the oviduct together the two follicles were also quite distinct, with separate blood supplies. This, together with the fact that in only a small percentage of double-yolked eggs is there any evidence of simultaneous ovulation, indicates that the fusion of follicles and a resulting common blood supply is by no means the usual cause for the production of a double-yolked egg. A simple normal follicle furnished the yolk with two germ disks; hence, the fusion of the occurred before the formation of the follicle."

From these observations it is concluded "(1) that double-yolked eggs sometimes represent a heightened rate of fecundity and sometimes an abnormally low physiological tone of the oviduct, (2) that even in cases in which the rate of fecundity is high the ovulations are not always simultaneous, (3) from the above it is apparent that the production of a double-yolked egg can seldom be explained as a result of simultaneous ovulations, and (4) in cases in which we have the best of reasons for suspecting simultaneous ovulations the two follicles may be quite distinct.

"It seems quite possible that a heightened rate of fecundity may result in every conceivable shortening of the period between ovulations consistent with the daily rhythm in the general physiological activities of the bird. Whether it results in the formation of a double-yolked egg is no doubt determined by the actual length of the period and the following response of the oviduct."

Crooked breast in fowls, C. D. Stewart (Ann. Sci. Bul. Roy. Agr. Col. Circnecster, No. 4-5 (1912-13), pp. 97, 98).—Investigations on this subject were made with the object of testing the effect of inbreeding.

It is concluded that "heredity seems ruled out as a cause of crooked breast, for all the chickens appeared perfectly normal when 10 weeks old, even though they were bred from stock selected with crooked breasts for three consecutive seasons." The results indicate that "perching is the chief, and probably the sole cause of crooked breast, and it seems to matter little whether the perches are round or square, large or small."

DAIRY FARMING—DAIRYING.

The production and consumption of dairy products, E. MERRITT (U. 8. Dept. Agr. Bul. 177 (1915), pp. 19).—This bulletin outlines the changes in the geographic distribution of the dairy industry since 1870 and gives information concerning the consumption of dairy products on farms and in cities.

Census data are presented which show that the number of dairy cows increased from 9,000,000 in 1870 to nearly 21,000,000 in 1910. The total butter production increased from 514,000,000 lbs, in 1870 to 1,620,000,000 lbs, in 1910; cheese production from 163,000,000 to 321,000,000 lbs. When geographic divisions are considered individually the increase for those east of the Mississippi River has not been so rapid as the increase for those west of that river, due primarily to the undeveloped condition of the West prior to 1870.

The number of cows per 1,000 population was 224.3 in 1910 and 225.5 in 1900; the average production of butter per capita was 17.6 lbs., which was a decrease of 2 lbs. as compared with the production in 1900; the average production of cheese per capita was 3.5 lbs., which was 0.4 lb. less than the production in 1900. In butter production the greatest per capita output is in the North Central divisions followed by the Pacitic division. The greatest per capita cheese production is in the East North Central division followed by the Middle Λt-lantic and Pacific divisions.

From replies to inquiries sent out to crop correspondents, it is estimated that the average person in a farm household consumes about \(^3\) qt. of milk per day, or a total yearly consumption of nearly 8,000,000,000 qts, for all farms reporting dairy cows. The daily butter consumption is \(^1\)0 lb, per person, and the total yearly consumption of farm families nearly 900,000,000 lbs.

The average number of quarts of milk required to make a pound of butter is estimated to be 9.6, varying from 8.1 to 10.7.

From replies furnished by boards of health it is estimated that the average per capita milk consumption in cities of 2,500 inhabitants or over is 112 qts, per year, and was slightly higher in cities of 25,000 inhabitants or over than in smaller cities. There was apparently less variation in milk consumption by months in the large cities than in the smaller ones. The fluctuations were generally less than 10 per cent.

International Union of Municipal Dairies (Molk. Ztg. [Hildesheim], 28 (1914), No. 49, pp. 941, 942).—An account of the first general meeting of the recently founded International Union of Municipal Dairies held in conjunction with the Sixth International Dairy Congress at Berne, June, 1914. Stockholm was selected by the meeting as the headquarters of the Union, which has for its object the general advancement of municipal dairying and the advising of its members as to methods of improving their business.

Value of vetch hay for milk and beef production, T. Wibberley (*Jour. Bd. Agr. [London]*, 21 (1914), No. 8, pp. 707, 708).—It is reported that for winter milk production, a daily ration consisting of 14 lbs. oat and vetch hay, 14 lbs. meadow hay, and from 70 to 84 lbs. giant rape or hardy greens was equal to 21 lbs. meadow hay, 56 lbs. roots, 3 lbs. corn meal, and 3 lbs. de-

corticated cotton cake. Methods of caring for the oat and vetch hay are described.

Palmnut kernel cake, J. A. Murkay (Jour. Bd. Agr. [London], 21 (1914), No. 8, pp. 697-701).—Methods of manufacturing this product are described and its composition and utility value for feeding purposes discussed. It is said that for feeding milch cows, palmnut kernel cake is a very good substitute for linseed cake. Cows may receive up to 5 lbs. per head per day.

Prolificacy of [the Guernsey] breed (Guernsey Breeders' Jour., n. ser., 7 (1915), No. 2, p. 17).—It is stated that of over 3.500 yearly official records that have been made by cows of the Guernsey breed, 39.6 per cent were made by heifers with their first calves, the average production being 8.641.91 lbs. of milk and 432.28 lbs. of milk fat, with an average percentage of fat of over 5. It was found that 310 cows had produced over 560 lbs. of milk fat, and 63 over 700 lbs. The greater proportion of these records were made after the cows had carried their calves four or five months, which fact is brought forward to refute any claims made against the breed regarding the fecundity of the high producers.

Comparative investigations into the performance of the breeds of cattle kept in the Province of Saxony, Prussia, H. Ebbindhaus (Deut. Landw. Tierzucht, 17 (1913), Nos. 40, pp. 473-476; 41, pp. 490-493; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 1, pp. 99-101).—In comparing the Simmental with the Lowland breeds of cattle it was found that with the former the live weight and gain in weight at the same age are the greater, that the yearly yield of milk is lower than in the Black- and Red-spotted Lowland cattle, but higher than in the Harz and cross-bred animals, that the fat content and the quantity of fat produced are greater than in the other breeds, and that the food consumption if expressed in Kellner's starch-values is essentially the same as in the other breeds. The relative milk yield is lower, but the milk-fat yield and increase of live weight are greater than in the other breeds.

Profitable and unprofitable cows, G. E. Wolcott (Maryland Sta. Bul. 187 (1914), pp. 115-134, figs. 10).—From records kept for the past three years of three Maryland cow-testing associations comprising more than 1.100 cows it is found that "the first year's records show that there was a wide variation in production between the individuals of the herd; some made large yields, while others were kept at a loss or barely paid for their feed. The records for the second year prove that by disposing of low producing cows, the average production of the herd was increased. In a number of herds increased production was brought about by feeding the individuals of the herd according to their ability to produce milk and fat. This was the case in herds where no abnormally low producers were found.

"The high producing cows were the most profitable....

"When the production of the individuals in the herd was known, the members of the associations were able to save the heifer calves from the best cows. One year's record work is not sufficient. When the herd has reached a high average of production constant selection is necessary to maintain this average.

"The association in Harford County shows a higher average production of butter fat than the other associations. This is due to the fact that several large herds of pure-bred cattle have been kept in the county for many years, and the pure-bred bulls from these herds have been used freely."

Testing and handling of milk and cream, R. McCann (Colorado Sta. Bul. 202 (1914), pp. 3-31, figs. 27).—This bulletin describes the methods and equipment used in the testing of milk and cream, and other matters relating to the

care and handling of cream. The procedure under the State laws relative to licenses, examinations, and inspections is also explained.

The encouragement of clean milk production, L. B. Cook (Mass. Bd. Agr. Circ. 38 (1915), pp. 9).—The author contends that the production of clean milk may be most readily encouraged by obtaining for the milk producer a reasonable margin of profit. It is shown that the average price paid for milk has not kept pace with the increasing cost of feeding stuffs. The grading of milk and the paying of prices according to grade would be an inducement along this line.

Ability of colon bacilli to survive pasteurization, S. H. Avers and W. T. Johnson, Jr. (U. S. Dept. Agr., Jour. Agr. Research, 3 (1915), No. 5, pp. 401–410, fig. 1).—The authors summarize the results of their studies, which are a continuation of work previously noted (E. S. R., 29, p. 73), as follows:

"The thermal death point of 174 cultures of colon bacilli isolated from cow feces, milk and cream, human feces, flies, and cheese showed considerable variation when the cultures were heated in milk for 30 minutes under conditions similar to pasteurization. At 60° C. (140° F.), the lowest pasteurizing temperature, 95 cultures, or 54.59 per cent, survived; at 62.8°, the usual temperature for pasteurizing, 12, or 6.89 per cent, survived. One culture was not destroyed at 65.6° on the first heating, but in repeated experiments it was always destroyed. There is a marked difference in the effect of heating at 60° and at 62.8°. Although there is only a difference of 2.8°. 87.3 per cent of the cultures which survived at 60° were destroyed at 62.8°.

"Considerable variation was found in the thermal death point of the colon bacilli which survived 62.8°. When the 12 cultures which survived were heated again at the same temperature, it was found that many did not survive and in each repeated heating different results were obtained. It seems evident that 62.8° maintained for 30 minutes is a critical temperature for colon bacilli. Among the 174 cultures studied all were found to have a low majority thermal death point, but were able to survive pasteurizing temperatures on account of the survival of a few cells.

"The colon test as an index of the efficiency of the process of pasteurization is complicated by the ability of certain strains to survive a temperature of 62.8° for 30 minutes and to develop rapidly when the pasteurized milk is held under temperature conditions which might be met during storage and delivery. The presence of a large number of colon bacilli immediately after the heating process may indicate improper treatment of the milk. If milk is pasteurized at a temperature of 65.6° or above for 30 minutes, we should not expect, from our results, that any colon bacilli would survive. Consequently under such conditions the colon test for the efficiency of pasteurization may be of value. It must be remembered, however, that a study of more cultures may reveal strains of colon bacilli that are able to survive this and even higher temperatures."

A bibliography of cited literature is appended.

A bacteriological study of blue milk, B. W. Hammer (*Iowa Sta. Research Bul. 15* (1914), pp. 467-481, figs. 7).—This is an account of a bacteriological study made of a sample of blue milk coming from a small Iowa farm, but which is thought to have become infected in the home of a customer.

Careful study of the organism involved proved it to be *Bacillus cyanogenes*. The organism isolated was examined morphologically, culturally, and biochemically. In its action on milk the organism was found to "produce a color in raw milk, in pasteurized milk, and in sterilized milk, although the color produced was markedly influenced by the previous treatment of the milk.

"Raw milk invariably developed a color sooner than pasteurized or sterilized milk and the color was also a brighter blue as a rule, being in some cases a sky

blue. Pasteurized milk inoculated with the organism developed a more intense color than sterilized milk, and in some cases (apparently influenced largely by the organisms surviving pasteurization) the color developed approximated that developed in raw milk. It was noticed that pasteurized milk which curdled quite rapidly, due to the production of acid, gave a good color development as a rule. In sterilized Lailk the color production was poor and is best described as a bluish gray rather than as a blue. In milk to which glucose was added before sterilization the color produced was more intense than in ordinary milk."

An increase in the intensity of the color was accompanied by an increase in acidity. The addition of *Bacterium lactis acidi* (o milk cultures of the blue milk organism (either freshly inoculated or a number of days old) resulted in a great increase in the intensity of the color.

"In no case was it possible to produce a blue color in milk held at 37° C, [98.6° F.], no matter what the previous treatment of the milk had been. The same temperature influence was found to hold for the various bouillons and it seems that the higher temperatures are unfavorable to the production of color. No aftempt was made to determine the lowest temperature which would prevent the formation of color, but both room temperature and 20° allowed the rapid production of color."

Pasteurization as well as sterilization favored the production of color uniformly throughout the sample, while in raw milk the color was in the main present only at the surface. Color production was found to occur in skim milk, in whole milk, and in cream, and in all cases the color production was greatest at and near the surface in the raw material. Attempts to produce a blue color in pieces of old cheese by the inoculation of the organism from agar slopes were unsuccessful.

A historical sketch of investigations of this organism is given, together with a bibliography of 12 references.

The use of Bacillus bulgarious in starters for making Swiss or Emmental cheese, C. F. Doane and E. E. Eldredge (U. S. Dept. Agr. Bul. 148 (1915), pp. 16, pl. 1, fig. 1).—This bulletin reports experimental work showing how to control undesirable fermentations and thus to provide a remedy for the most serious troubles which occur in making Swiss or Emmental cheese.

Many cultures of *B. bulgaricus* obtained from different sources were used and found to vary widely in their ability to suppress gas-forming bacteria, some proving efficient when the starter was less than 2 per cent of the total amount of milk used, whereas other cultures were not efficient with less than 4 per cent. Ordinary lactic acid cultures were not successful in preventing gas formation. Experiments with *B. bulgaricus* starters in a commercial factory demonstrated that the maker of Swiss cheese can control the fermentations with some cultures of this organism; that a good quality of Swiss cheese can be made in winter as well as in summer; and that it is probably practicable to make cheese once a day instead of twice a day, as has been necessary in the past.

Methods are described for preparing and keeping cultures, and a new type of starter-can for carrying starter is illustrated and described. This starter-can may be used for other dairy purposes with whey starters.

Influence of the flora of the cheese rind on the proteolysis and fat-splitting in the inner portion of the cheese, O. Gratz and I. Szanyi (Kisérlet. Közlem., 17 (1914), No. 5. pp. 801–834, figs. 16).—From analyses of different portions of the cheese it was concluded that the flora of the outer portion do not participate in the proteolysis and fat-splitting of the inner portion.

VETERINARY MEDICINE.

Synopsis of parasitology of man and the domestic animals, L. Gedelst (Synopsis de Parasitologie de l'Homme et des Animaux Domestiques, Lierre; Jos. Van In & Co., 1911, pp. XX+332, figs. 327).—The first part of this work deals with the vegetable parasites (pp. 1-29). The animal parasites are taken up under the headings of Protozoa (pp. 30-64), worms (pp. 65-139), and arthropods (pp. 140-252). Brief descriptions are given of the genera and higher groups of which the parasitic species are listed. Host lists of parasites are given for man, horse, ass, mule, cattle, carabao (Buffelus indicus), zebu (Bibos indicus), elephants (Elephas indicus and E. africanus), camels (Camelus bactrianus and C. dromedarius), reindeer (Tarandus rongifer), sheep, goat, swine, dog, cat, guinea pig, rabbit, chicken, turkey, guinea fowls (Numida meleagris and N. ptilorhyncha), pheasant, pigeon, peacock, duck (Anas boschas domestica), goose (Anser cinevens domesticus), swan, and ostrich.

A complete index is included.

Handbook of veterinary obstetrics, L. Franck (Handbuch der tierärztlichen Geburtshilfe. Berlin: Paul Parcy, 1914, 5. rev. and cal. ed., pp. X+740, figs. 335).—This work deals with anatomy, physiology, and pathology as related to gestation and parturition, diseases that follow, diseases and abnormalities of the young, etc.

Regulations governing the meat inspection of the United States Department of Agriculture (U. S. Dept. Agr., Bur. Anim. Indus. Order 211 (1914), pp. 97).—The regulations here promulgated became effective November 1, 1914, with the exception of regulation 27, relating to the inspection of imported meats, which became effective January 1, 1915.

The new regulations codify the many amendments and rulings made since the adoption of the old regulations on April 1, 1908, and also add to the requirements a number of features suggested by eight years' experience in meat inspection and conforming with recent scientific discoveries. The more important changes made relate to the condemning of diseased animals prior to slaughter, withdrawal of inspection from inspected establishments that violate the regulations, the permission of the sale of second-class sterilized meat on a plan somewhat similar to that followed by the German and Austrian Governments, more stringent regulations governing the inspection of carcasses of hogs suspected of hog cholera, the safeguarding of inspection marks, prohibition of raw pork in certain food products, a redraft of sanitary regulations, and regulations regarding imported meat.

Guide for meat inspectors, R. OSTERTAG, trans. by E. V. WILCOX (New York: William R. Jenkins Co., 1915, pp. 7+258, figs. 158).—The first English edition, translated from the twelfth edition of the author's Leitfaden für Fleischbeschauer.

In an introduction the author discusses briefly the nature and purpose of ante-morten and post-mortem inspection. The several chapters of the work take up the subject as follows: Name and normal character of organs and parts of animals, including the determination of the species from sample parts (pp. 3-51); functions of the animal body with special reference to the blood and lymph circulation and to the chief evidences of health in living animals (pp. 52-60); ante-mortem inspection, including the means of identifying animals (pp. 61-76); methods of slaughtering, cuts of meat, live and dressed weight, post-mortem changes in meat, and the recognition of the age and sex of slaughtered animals (pp. 77-92); routine of meat inspection (pp. 93-101); nature and characteristics of the diseases and defective conditions of most

importance in meat inspection (pp. 102-195); preservation of meat—tanking of condemned meat (pp. 196, 197); legal regulation of meat inspection in the United States (pp. 198-240); and educational requirements for inspectors (pp. 241-254). All material not applicable to American conditions has been omitted. Some 80 pages relating to German laws, regulations, and diseases which do not occur in the United States have thus been replaced with American laws, regulations, and educational requirements for inspectors, and matter relating to diseases not discussed by the author. The most recent regulations of this Department governing meat inspection are noted above.

Handbook of meat inspection, R. VON OSTERTAG (Handbuch der Fleischbeschau, Stuttgart: Ferdinand Enke, 6, rer, and enl. ed., vol. 2, pts. 1 (1910), pp. X11+\forall 12, figs. 120; 2 (1913), pp. X11+890, pts. 3, figs. 258).—The sixth revised and enlarged edition of this work (E. S. R., 16, p. 96).

Stock poisoning plants of California, H. M. Hall and H. S. Yates (California 8ta, Bul. 249 (1915), pp. 219-247, figs. 7).—Among the more important poisonous plants here dealt with are the water hemlock (Cicuta 8p.), death camas (Zygadenus renenosus), larkspurs (Delphinium 8pp.), milkweeds (Asclepias 8pp.), lupines (Lupinus 8pp.), loco weeds (Astragalus 8pp.), etc. A bibliography is appended.

Some observations on arsenical dipping fluids, 1. Comen (Agr. Gaz. N. 8, Wales, 25 (1914), No. 11, pp. 937-944).—This paper discusses the preparation of standard dip fluid and the maintenance of standard strength.

[First biennial report of the office of state veterinarian], W. H. LYTLE (Bien, Rpt. Oreg. Live Stock Sanit, Bd., I (1913-14), pp. 14-41).—This report deals with milk and meat hygiene; diagnostic serums; curative and preventive vaccines; and the various infectious diseases which occurred in Oregon during the year—Rabbit eradication is also briefly discussed.

Report of proceedings under the diseases of animals acts for the years 1912 and 1913 (Dept. Agr. and Tech. Instr. Ireland, Rpt. Diseases Anim., 1912, pp. 55; 1913, pp. 63, pl. 1).—These annual reports (E. S. R., 27, p. 781) deal with the occurrence of the infectious diseases of domestic animals scheduled under the diseases of animals acts in Ireland. Much statistical data relating thereto are appended to the reports.

Determination of the protein content of the serum of domesticated animals by refractometry, G. CSONKA (Közlem, Összchasonl, Élet es Kortan Köreböl, 10 (1913), No. 7-8, pp. 257-292, figs. 2; abs. in Berlin, Tierärztl. Wehnschr., 29 (1913), No. 46, p. 820).—The refraction coefficient of the blood serum of sound animals is very variable, but between 1.345 and 1.35185. An abnormal increase in the refraction occurs when the animals receive too little water or lose much water, as in the dysentery noted in intestinal forms of hog cholera. An abnormally low coefficient is noted in cardiac and renal insufficiency, in anemic and cachectic conditions, especially in distomatosis of sheep.

The refraction is a sensitive method for detecting hydramnia. In heart diseases it is possible by the method to note the variation in the utilization of feed-stuffs by the circulating blood and also to determine the variation in velocity of the circulation. The cryoscopic method is preferable for determining the degree of renal insufficiency.

Anthrax or charbon.—Points of popular interest, H. Morris (Louisiana Stas. Bul. 152 (1915), pp. 3-11, figs. 3).—This bulletin answers in brief form questions regarding the nature and control of anthrax.

Foot-and-mouth disease (Jour. Bd. Agr. [London], 21 (1915), No. 10. pp. 873-877, pls. 2).—A brief summarized account.

Dealing with foot-and-mouth disease, W. J. Hartman (Breeder's Gaz., 67 (1915), No. 7, pp. 331, 332, figs. 9).—It is pointed out that while the disease

may not be fatal in communities where corn silage, roots, and other soft feeds can be fed, this is not true in the western States where cattle subsist on dry, hard feed through the winter. The author states that more than 30 of some 200 infected cattle died of the disease in the stockyards at Glendive, Mont., during the first 10 days' progress of the disease in November. In sheep and hogs, of which more than 200 of the former and about 30 of the latter were infected at Glendive, the disease was much more severe than in cattle.

A study of the specific reactions for the diagnosis of glanders, V. A. Moore and C. P. Firch (*Rpt. N. Y. State Vet. Col., 1911–12, pp. 51–69*).—Because of the discrepancy sometimes observed in the diagnostic tests it seemed necessary to make a careful investigation of the different methods and to determine so far as possible their relative value. The work was carried on with the cooperation of the New York State Department of Agriculture.

The discrepancies which are reported from different laboratories with the agglutination test for glanders are believed to be usually due to the test fluid used in one or the other laboratory. Thus it is that cultures isolated from different sources show a marked difference in their agglutinating properties, and, furthermore, some cultures that agglutinate satisfactorily later lose their agglutinating properties. There are also cultures of *Bacillus mallei* which will agglutinate with the serum from healthy horses. No advantage could be noted in using a test fluid prepared from several strains of *B. mallei*.

"The discrepancies which occur between the results of the sera and malfein tests can often be explained on the ground that the sera were taken from horses previously tested with mallein or treated with vaccine. Miessner (E. S. R., 20, p. 3851 calls particular attention to the fact that when the agglutination test is used in the control of glanders the use of mallein should be prohibited. Our experience shows that the indiscriminate use of vaccines has an equally deleterious effect upon the accuracy of the sera tests."

In all probability different tests depend upon the presence of different specific antibodies or products given off by the tissues as the result of the stimulation of the tissues by the glanders organism. The bodies upon which the serum reactions depend do not appear to occur in the blood at the same time.

The complement fixation test "does not possess, because of the greater chance for error owing to its complications, any advantage over the agglutination test in diagnosing occult glanders." The ophthalmic mallein test has a definite value in the diagnosis of occult glanders and it can be used at times when the subcutaneous method is precluded. The subcutaneous method under suitable conditions is quite as accurate as the ophthalmic mallein test.

"As with the sera test, mallein can not be relied upon in the diagnosis of glanders in animals that have previously been injected with vaccine. In practice the use of mallein has this advantage, that it is a field method and the conditions governing the test and the interpretation of the reaction are left to the practitioner who is familiar with the case. Further, the elements of error are in proportion to the complications of the method. In confirmation of the results of positive reactions by means of post-mortem examinations it is very important not to mistake lesions caused by parasites for those of glanders. Olt has pointed out that parasitic lesions often occur in the lungs and liver which are easily mistaken for glanders nodules. The diagnosis can be made from a microscopic examination of the properly stained sections. In case of lesions due to parasites there is a varying degree of eosinophilia which is absent in glanders. In our experience we have found lesions of a parasitic nature in the lungs, liver, spleen, and lymphatic glands that resembled glanders macroscopically and which in several cases were supposed to be true glanders lesions."

The insect carrier and the reservoir of the virus of oriental sore.—Hypothesis and preliminary experiments, E. Sergent, G. Lemaire, and G. Senevet (Bul. Soc. Path. Exol., 7 (1914), No. 7, pp. 577-579; abs. in Rev. Appl. Ent., 2 (1914), Ser. B. No. 12, pp. 199, 200).—The authors have found that Phlebotomus minutus africanus not only feeds upon the gecko (Tarcatola mauritanica) but also bites man. From 19.7 per cent of the geckos examined they have been able to prepare pure cultures of a Leptonomas which resembles that obtained from cultures of oriental sore (Biskra boil, tropical ulcer). References are given to the literature on the subject.

New serum and liver substances as levuloses in trypanosomiasis, K. Schern (Jour, Med. Research, 30 (1914), No. 3, pp. 533-540). Previously noted from another source (E. S. R., 30, p. 381).

The value of physical examination and clinical diagnosis in the control of tuberculosis in cattle, V. A. Moore (Rpt. N. Y. State Vet. Col., 1911-12, pp. 169-175).—The author concludes that a physical examination will enable a skilled examiner to detect advanced cases of tuberculosis in cattle and the presence of lesions in less advanced cases so that the suspected animals can be removed. If properly carried out, it will also detect from 80 to 90 per cent of the animals which are actually spreading the virus and a large percentage of those about to become spreaders but which have not eliminated the specific bacteria. It will not, however, detect more than from 1 to 5 per cent of the infected animals at any one time, and can not be relied upon to detect all infected cattle. For this reason its value is very largely restricted to the intraherd control of the disease, while in interherd control tuberculin is the only diagnostic agent we have.

The intrapalpebral and intradermic palpebral tuberculin tests, G. Moussu (Rec. Méd. Vél., 91 (1914), No. 13, pp. 425-434, figs. 5; abs. in Jour. Compar. Path. and Ther., 27 (1914), No. 3, pp. 265, 266).—The objections which may be raised to the use of the subcutaneous tuberculin test are discussed at some length. From the practitioner's standpoint are mentioned the amount of trouble involved in taking the temperatures; the possibility of noting temperatures incorrectly; the difficulty of interpreting irregular results; the necessity of keeping the animals indoors, which is in itself sometimes sufficient to cause a rise of temperature; the impossibility of applying the test to animals in a febrile condition; and the necessity of carrying out the test at certain hours at the risk of making serious errors. These are not objections to the method itself, but are due to conditions under which the test is carried out.

On the side of the owners of cattle the following objections may prevail: (1) A reduction in the milk yield; (2) danger of specific mastitis; and (3) danger of aggravating the general condition of the diseased animals. In view of these objections the local tests, intradermic and intrapalpebral, are considered more useful, more practical, and more economic from the owner's point of view and more remunerative than the subcutaneous method from the practitioner's point of view.

There is no difficulty in applying the test, provided a suitable syringe is used; "this should have a capacity of 1 cc. The needle should be about 1½ cm. in length and 7 mm. in diameter. The barrel of the syringe should be graduated into tenths, and the piston rod should have a traveling stop on it. It is advised that 0.1 cc. of ordinary tuberculin should be used, special tuberculin of any kind not being required.

"When the test has been properly carried out a little swelling should be formed in the subepidermic tissue, about the size of a large lentil, where the tuberculin is injected. Reactions are said to make their appearance more rapidly and more clearly the more recent and the more limited the lesions.

After 36 to 48 hours the eyelid becomes swollen, edematous, and slightly tense, and the eye appears sunken. The tissues lose their suppleness, the skin is rigid and sometimes reddish and moderately sensitive. There may be slight lachrymation. Even a moderate reaction is rendered quite obvious by comparison with the opposite eye.

"When the palpebral and caudal tests are carried out simultaneously they agree exactly, and should one of the tests have been improperly carried out the other gives a positive result. An important practical point is that the tests are complementary, or they correct each other. For those who find the intradermic palpebral test too delicate a manipulation, a subcutaneous injection of $\frac{1}{8}$ to $\frac{1}{2}$ cc., or more, of tuberculin may be made into the upper or lower cyclid, this yielding a local reaction as characteristic as the intradermal test. The author has carried out tests upon about 60 animals, using different doses of tuberculin, and he has found that as good results can be obtained with $\frac{1}{8}$ cc. as with $\frac{1}{2}$ cc. If, however, the larger dose be used, the test approximates to the subcutaneous method in that it is likely to produce a temperature reaction with the accompanying disadvantages. The method of testing is held to be free from all the objections that have been raised above against the subcutaneous method."

The author's practice is to make an injection into both cyclids.

Avian tuberculosis, F. S. Jones (*Rpt. N. Y. State Vet. Col., 1911–12, pp. 159–164, pls. 5*).—A review of the literature with a history of a recent outbreak in New York State. The autopsical findings with a White Leghorn pullet are given in detail with reproductions of photographs of the affected organs.

Actinomycosis or Iumpy jaw, R. R. Dykstra (Kansas Sta. Circ. 41, pp. 3).— A popular account.

Brisket disease (dropsy of high altitudes), G. H. Glover and I. E. Newsom (Colorado Sta. Bul. 204 (1915), pp. 24, figs. 5).—This is a preliminary report of studies of a disease which occurs in cattle at high altitudes in Colorado, the principal symptoms of which are swelling of the brisket and the loose tissues under the jaw, usually diarrhea, and a moist cough, with gradual emaciation and death. The disease which is chronic in character is fatal in practically all cases. On autopsy the most marked symptoms are general dropsy, enlarged and hard liver, and dilated heart.

Reports are presented of 31 cases under observation. Six cases which were shipped to a lower altitude (about 5,000 ft.) all recovered without other treatment, although it is believed that they would have died had they not been shipped.

"It appears to be caused by an exhaustion of the heart muscle associated with a varying degree of dilatation and hypertrophy and this being brought about by exertion before acclimatization at high altitudes, or in the case of calves, inherited cardiac weakness. Medical treatment has so far proved of little avail, but where possible shipping the affected animals to a lower altitude is recommended. Preventive measures include the use of bulls that have been raised at altitudes of 8,000 ft, or more, with a view to building up a hardier strain of cattle, also the curtailment of indiscriminate shipping of low altitude cattle to high altitudes."

[A disease of cattle reported in Guam which resembles Texas fever], J. B. Thompson (Guam Sta. K,... 1914, pp. 22-23, figs. 3).—This is a report of further studies (E. S. R., 31, p. 482) of a disease of cattle reported in Guam.

It is stated that all the imported cattle have again been subject to attacks of fever at various times during the year. Several affected animals succumbed to the disease. The principal symptoms observed in a cow which succumbed March 8 were extreme emaciation, a deprayed appetite, and a more or less inter-

mittent fever. A post-mortem examination showed lesions indicative of Texas fever. Temperature charts of three animals are presented.

"The immunization of susceptible cattle from the United States by the method of controlling tick infestation has not proved complete or reliable, but results in what appears to be a chronic form of the disease. In the introduction of cattle into Guam the great importance of securing immune stock is plainly recognized."

Diseases of swine, S. S. Buckley (Maryland Sta. Bul. 185 (1914), pp. 59-67).—A brief summarized account is given of the diseases of swine most commonly met with in Maryland.

Hog cholera, L. L. Lewis, W. P. Shuler, C. H. McElroy, and L. B. Ritter (Oklahoma Sta, Bul. 104 (1914), pp. 30, figs. 10).—Following a general statement relative to log cholera in Oklahoma and a description of the disease and its distribution, the findings on post-mortem, and methods of producing and using antilog-cholera serum, some experimental data collected during routine work in this branch are reported.

Examinations of the blood showed that in uncomplicated cases of hog cholera there is a general tendency toward a reduction of red and white blood cells and in the amount of hemoglobin. In one case the crythrocytes were reduced from 5.740,000 to 2.000,000 per cubic millimeter in 12 days as a result of inoculating virus and a reduction of the leucocytes from 25,000 to 7,000 per cubic millimeter. In some observations on the changes produced in the blood by hyperimmunizing with the slow or subcutaneous method and successive bleedings from the tail at intervals of from 8 to 12 days, it was found that the "introduction of the virus appears to lessen very materially the red cell count, but does not affect the leucocytic count to the same extent. The amount of blood taken at each bleeding was approximately 750 cc. (6 cc. per pound of weight)." Neither the leucocytes nor the percentage of hemoglobin appears to be affected to a marked degree by the process. In studying the effect of the intravenous method of inoculation the data show "that there is a reaction in from one to four days after immunizing, the temperature rising from 1 to 5° F. There does not appear to be any marked effect on the percentage of hemoglobin. The white blood corpuscles are increased in each case after the injection of the blood, and as a rule a slight rise in the number of red cells will be noted."

Quinin hydrochlorate was studied as regards its influence on the course of hog cholera. "So far as the four cases studied are concerned, quinin in the amounts given failed to influence the course of the disease, but did appear to have some effect on the period of incubation. The blood count in these cases was variable, but the general tendency of all the hogs was to show a lower count toward the termination of the disease. Temperatures were variable and did not show any effect of the administration of the quinin solution. Quinin hydrochlorate was administered hypodermically in 14.3-grain doses. All of the pigs were killed as their physical condition indicated that death would occur within a short time." A few cases showing the effect of intravenous injections of cold physiological salt solution and a large amount of vaccine in one case are also reported upon.

"Experiments were conducted in connection with the hog cholera serum work to determine the time after hyperimmunizing before the blood from the hypered or treated hog ceases to be virulent to normal hogs. The test was planned so that checks could be had on the virulence of blood used for hypering and to keep the test pigs in pens free from any outside infection. . . . The result of one of the tests shows that blood drawn 24 hours after hypering does not contain virulent material; also that the blood drawn after four or five days is not sufficiently potent as a vaccine to be relied upon to protect a hog

when given in the usual amount against a fatal dose of virus administered later." In other experiments it was planned to use the blood from a pig which had been hyperimmunized for two days in the same manner as a vaccine was used. "The pig was hyperimmunized by giving 5 cc. of virus per pound of weight; weight of pig about 60 lbs. The blood was injected intravenously, and 42 hours later the pig was killed and the blood secured was treated as vaccine; that is, it was defibrinated and had 0.5 per cent carbolic acid added as a preservative." This blood tested on four healthy pigs showed no ill effects even though they were given 1 cc. of fresh hog cholera virus nearly a month later. In giving virus intravenously it was found best to cool it to near the freezing point. This causes in some cases a rise in body temperature and in others a reduction.

Analyses made of the urine of hogs during the course of immunization by the intravenous route indicated very little variation from the normal composition. In one instance albumin was noticed and indican was found in several cases.

Serum as a factor in inter-herd control of hog cholera in New York, R. R. Birch (Rpt. N. V. State Vet. Col., 1911–12, pp. 131–139).—A brief discussion of the serum and serum simultaneous method of treatment, the factors instrumental in spreading hog cholera in the State, especially the feeding of garbage, and the desirability of permanent immunity in hogs.

It is pointed out that "serum treatment is a valuable aid to sanitation, but is not a substitute for it. Conditions in New York suggest that the sooner active measures are taken to suppress hog cholera the cheaper and more effective these measures will be." "Correct diagnosis is important. Especially must the disease be differentiated from food poisoning."

Notes of the hog cholera conference at Purdue University, December 18, 1913, C. H. CLINK (Indiana Sta. Circ. 48 (1915), pp. 27, fig. 1).—A detailed account of the meeting, including the questions asked and the answers given.

Report of veterinarian, C. A. CARY (Alabama Col. Sta. Rpt. 1914, pp. 17, 18).—In the work carried on during 1914, particular attention was given to the kidney worm (Stephanurus dentatus). It was found in the kidneys, kidney fat, and lumbar muscles in every hog that was examined which had paraplegia. It is stated that at present no remedy can be given that will eliminate these worms from the affected parts.

New pig disease in Ireland, W. Frost (U. S. Dept. Com., Com. Rpts., No. 19 (1915), p. 333).—A disease of swine known locally as "purple fever" which recently appeared in Mayo and Sligo Counties, Ireland, is thought to be a form of swine erysipelas.

Canine medicine and surgery, C. G. Saunders (Chicago: Amer. Jour. Vet. Med., 1915, pp. 249. figs. 8).—A work intended mainly for the use of senior students and practitioners of veterinary medicine. It presumes a knowledge of pathology, histology, and anatomy, and aims to deal only with the clinical aspect of the various diseases. The first part (pp. 7–179) deals with diseases; the second part (pp. 180–242) with surgical operations.

Infectious coryza of fowls, G. Vallillo (Clin. Vel. [Milan], Rass. Pol. Sanit. e 1g., 37 (1914), No. 3, pp. 93–111, figs. 2; abs. in Vel. Rec., 27 (1914), No. 1363, pp. 121, 122).—This disease of fowls has prevailed for a number of years in the Lago di Lecco district of Italy. It takes the form of a catarrhal infection of the upper air passages, and in consequence of its high mortality, especially among the younger birds, causes considerable loss to poultry breeders. The disease is said to be caused by a short ovoid bipolar bacillus which is often united in chains of two or three together. To all appearances it is a variety of Bacillus avisepticus. As a rule the disease ends with death after a duration

of from six weeks to three months. Only adult, strong, and well-nourished birds recover without serious injury.

Coccidiosis in poultry and game birds, H. B. FANTHAM (Jour, Bd. Agr., [London], 21 (1915), No. 10, pp. 889-899, figs. 2).—A summarized account, including preventive measures.

RURAL ENGINEERING.

Engineering geology, II. Ries and T. L. Watson (New York: J. Wiley & Sons, 1914, pp. XXVI+672, pls. 104, figs. 225).—In an exposition of the fundamental principles of geology the authors have attempted primarily to emphasize the practical application of the topics treated to engineering work. The book begins with an extensive discussion of petrographic subjects, such as the properties of common rock-forming minerals and the general character, mode of occurrence, origin, structural features, and metamorphism of rocks. Considerable space is devoted to rock weathering, soil formation, and the occurrence, distribution, and movement of surface and underground waters. Other subjects more closely related to structural engineering which are taken up in more or less detail are landslides; wave action and shore currents; lakes; glacial deposits; building stone; limes, cement, and plaster; clay and clay products; coal; petroleum, natural gas, and other hydrocarbons; road foundations and materials; and ore deposits.

The principles of irrigation practice, J. A. Widtsoe (New York: The Macmillan Co., 1914, pp. XXVI+\396, figs. 179).—This popular treatise represents an attempt to develop the principles underlying the correct use of water in irrigation for the use of farmers. It contains the following chapters: The meaning of irrigation: soil moisture; the soil as water reservoir; saving water by cultivation; soil changes due to irrigation water; conditions determining the use of soil moisture by plants; the water-cost of dry matter; crop development under irrigation: the time of irrigation; the method of irrigation; crop composition; the use of the rainfall; irrigation of cereals; alfalfa and other forage crops and pastures; sugar beets, potatoes, and miscellaneous crops: fruit trees, other trees, and shrubs; the duty, measurement, and division of water; overirrigation and alkali; irrigation in humid climates; irrigation tools and devices; the history of irrigation; and permanent agriculture under irrigation

Underground water resources of the Coastal Plain of Georgia, L. W. Stephenson, J. O. Veatch, and R. B. Dole (U. S. Geol. Survey, Water-Supply Paper 341 (1915), pp. 539, pls. 21, figs. 4).—This report embodies the results of studies of the geology and underground water resources of the Coastal Plain of Georgia, the latter being discussed for each county in the area, including various analyses.

Geology and water resources of Tularosa basin, New Mexico, and adjacent areas, O. E. Meinzer and R. F. Hare (U. S. Geol. Survey, Water-Supply Paper 343 (1915), pp. 317, pls. 19, figs. 51).—This report, prepared in cooperation with the New Mexico Experiment Station, deals with the physiography, geology, and water resources of an area of approximately 6,000 square miles in New Mexico, and also takes up in some detail such related subjects as quality of water, irrigation, and soil and native vegetation in relation to water supplies.

In the valley fill it is stated that supplies sufficient in quantity for domestic use and for stock can be obtained practically everywhere. In the waters of the valley fill of the northern area there is no sodium carbonate but there are generally large amounts of sodium chlorid and also important amounts of sodium

sulphate and magnesium sulphate, thus emphasizing the necessity for caution in the use of these waters for irrigation to prevent accumulations of alkali.

In the Cretaceous area many wells have been sunk, both deep and shallow, from nearly all of which sufficient water for domestic use and stock supply is obtained. "The water from most of the springs and wells of moderate depth is hard but of good quality for irrigation and fairly satisfactory for drinking and household use, but the water from the wells in certain localities, notably the immediate vicinity of Carrizozo, is too highly mineralized for drinking or household use and of doubtful character for irrigation."

In the Carboniferous rocks and underlying sediments of the northern plateau section of the basin, the agricultural problem is to obtain water for domestic use and live stock. "Some of the waters, especially those from shallow sources, are fairly satisfactory for domestic use and for drinking, but many are either undesirable or wholly unlit for these uses. . . .

"The soils that are more or less suitable for agriculture can be grouped as the red adobe soils, the gypseous soils, the more ordinary loam soils, . . . and the sandy soils. The soils that produce more or less desert vegetation but are practically worthles for agriculture can be grouped as the gravelly and bowldery deposits, the quartz sands of the dune areas, the gypsum sands, the alkali clays, and the waste in the crevices of the lava beds."

Analyses of samples of the soils of the area made at the station showed them to be generally deficient in nitrogen. It is stated that the phosphoric acid content compares fairly well with that usually found in soils of average fertility. The potash content was variable but was on the whole small as compared with the content of soda and other soluble salts. It is stated that the soils are in poor tilth and need deep cultivation and green manuring.

Analyses further showed large amounts of sulphates and calcium and only very small amounts of carbonates or bicarbonates. In a few cases an excess of chlorin over sodium was found, indicating the presence of either magnesium chlorid or calcium chlorid. It was also found that the average amounts of alkali within the capillary limits increased gradually with decreasing depth of ground water. "Wherever the water table is within about 12 ft. of the surface the soil is liable to contain harmful amounts of alkali, and the nearer the surface the ground water stands the greater is the danger from alkali. In all of the samples taken in localities where the depth to water is less than 10 ft, the alkali content was greater in the first foot of soil than farther down. . . . Sodium chlorid and other alkalis are distributed in appreciable quantities over much of that part of the interior gypseous plain where the water table is at present too low to have any influence on surface conditions."

The distribution of zones of vegetation was found to be influenced by the amounts of rainfall and flood waters and by the depths to ground water. It is stated that only about one acre in 1,000 is under irrigation in the basin. Surface waters have been used to considerable extent with more or less success and the areas prospectively available for irrigation with well waters are outlined as follows: The shallow-water tracts in the Cretaceous area north of Three Rivers, including land adjacent to Nogal Arroyo and near Carrizozo and Oscuro and the surrounding country; the shallow-water tracts in the valleys of the Sierra Blanca and Sacramento Mountains and adjacent foothills, especially in the valley of Three Rivers; a belt on the east side of the basin extending from the lower part of the younger lava bed to some distance south and southwest of Dog Canyon, limited on the north, east, and south by the depth to water and on the west by the alkali and gypsum in the soil; and a narrow belt on the west side of the basin extending from the vicinity of Mound Springs to the meadow

south of the white sands, limited on the north, west, and south by the depth to water and on the east by the alkali and gypsum in the soil.

It is stated that most of the pumping plants thus far installed in the basin are operated by windmills, gasoline engines, or electric motors, but that horsepowers and steam engines are also in use.

"Because of the limitations in regard to both quantity and quality of the underground supply and because of the cost of pumping, it is doubtful whether heavy irrigation, such as is commonly practiced in the Rio Grande Valley and other irrigation districts, will be feasible, except very locally, in Tularosa Basin; but the sparing use of well water to supplement rainfall and flood waters contains more promise and should be given a thorough trial." It is stated that a small amount of well water properly applied as supplemental irrigation with careful methods of farming will add greatly to the yield of certain crops, particularly forage and other field crops, vegetables, and fruit.

The use of surface water free from bacteria as drinking water, Hauri (Pharm. Zentralhalle, 55 (1914), No. 40, pp. 861-866).—The author describes briefly experiments which, in his opinion, demonstrate the feasibility of using definite quantities of calcium hypochlorite in the sterilization of surface water for drinking purposes in emergency cases and at the same time using alum for the precipitation of suspended matter and colloidal matter in solution. The taste may be more or less removed by filtration through iron filings.

The chemical disinfection of water, E. B. PHELES (Pub. Health Rpts. [U. S.], Reprint 225 (1914), pp. 8, figs. 3).—This paper describes methods and simple apparatus for applying the hypochlorite process in the purification of small community and private water supplies.

Bleaching powder or calcium hypochlorite, it is stated, should be bought on specification to contain not less than 33 per cent available chlorin. The American product is considered less likely to give troublesome odors to the water than the imported product. The minimum quantity of solution which can be properly controlled and measured is said to be about 15 gal. per hour. For small plants hand mixing is said to be satisfactory. The solution in the mixing tank is allowed to stand four hours or longer and may then be drawn off into the solution tanks, where it is diluted to the proper strength. A set of 6 or 7 vinegar barrels properly connected with galvanized iron piping and well painted on the outside with asphaltum or some good mineral paint makes a satisfactory temporary plant. Small plants are said to be most easily run on the constant strength basis.

"On the basis of 33 per cent bleaching powder (which allows for losses in extraction) 25 lbs. per million gallons of water will give one part per million of available chlorin. Clear, colorless ground water, free from iron, or the clear water of large lakes requires, as a rule, from 0.1 to 0.3 parts of chlorin or 2.5 to 7.5 lbs. of bleaching powder per million gallons. Mountain streams and upland water free from color and turbidity and without storage in ponds require from 0.2 to 0.5 parts. Colored river waters, swamp waters, and highly polluted surface waters may require as much as one part or more."

Profile surveys in Willamette River Basin, Oregon (U. S. Geol. Survey, Water-Supply Paper 349 (1914), pp. 8, pls. 16).—This report, prepared under the direction of R. B. Marshall, describes the general features of the Willamette River Basin and gives plans and profiles of streams therein.

Profile surveys in Wenatchee River Basin, Washington (U. S. Geol. Survey, Water-Supply Paper 368 (1914), pp. 7, pls. 8).—This report, prepared under the direction of R. B. Marshall, describes the general features of the Wenatchee River Basin and gives a plan and profile of Wenatchee Lake. Wenatchee River, and certain tributaries.

Land drainage in Maryland, J. R. HASWELL (Maryland Sto. Bul. 186 (1914), pp. 69-113, figs. 9).—This bulletin is based upon the work of the Drainage Investigations of this Office in the State of Maryland. Its purpose "is to show briefly what properly constructed drainage improvements have accomplished and will accomplish in developing farm lands in the State, and to offer suggestions that may assist in the proper application of drainage in all parts of Maryland."

There are 517 square miles of swamp and marsh land in the State, the greater part of which occurs in the 2.650 square miles of coastal plain. Under "benefits of drainage" the results obtained in different localities in the State are briefly reported. The author also takes up briefly land drainage for mosquito control.

In an appendix is given the text of the Maryland drainage law.

Concrete in drainage and irrigation, P. T. LIBBERTON (Trans. Amer. Soc. Agr. Engin., 7 (1913), pp. 135-145, figs. 6).—The author discusses the use of concrete in irrigation and drainage structures and points out that its successful use in these depends largely on the proper selection, proportioning, and mixing of materials.

Progress report on cause of disintegration of cements by alkalis, K. Sterk (Wyoming Sta. Rpt. 1914, pp. 148-158, figs. 11).—In the course of this work the following compounds have been isolated; (1) Calcium sulphate, (2) calcium hydroxid, (3) calcium carbonate, and (4) one silicate of which the composition has not yet been determined.

"The calcium sulphate hydrated salt was found to be a reaction product between cement and the sulphates of magnesium and sodium. This salt was found deposited in crystalline form from solutions of varying strength, from 1 per cent to 10 per cent. The crystals were in all cases found on the surface of the blocks of cement, deposited either as single crystals or as groups of crystals radiating from a center. . . . In some cases the sulphate of calcium was deposited in amorphous form. This was more noticeable in cements low in lime content. The microscopic examination of the cements which had a great abundance of crystals on the surface did not show their presence inside the cement blocks. The same was found to be true in case of the other compounds mentioned. . . .

"The calcium hydroxid was obtained from cement immersed in solutions of chlorids of magnesium and sodium, also from solutions containing both these chlorids. Also this compound was deposited on the surface in crystals about $\frac{1}{3}$ in. wide and about 1.64 in. thick. . . .

"The calcium carbonate was obtained in amorphous form only from cements in solutions of sodium carbonate."

Further studies were made of the effect of alkali salt solutions on the strength of cements. It was found that high silicia cement when immersed in a 5 per cent solution of equal parts of sodium carbonate, sodium chlorid, and sodium sulphate was reduced in tensile strength 3.5 per cent after 12 months and 14.2 per cent after 26 months and was increased in compressive strength 10 per cent after 12 months and 16.3 per cent after 26 months.

The tensile strength of neat Portland cement when immersed in a 5 per cent solution of sodium chlorid, sodium sulphate, magnesium chlorid, and magnesium sulphate was increased 101.3 per cent after 12 months and decreased 13.3 per cent after 26 months and the compressive strength was increased 46 per cent after 12 months and decreased 25.7 per cent after 26 months. In a similar set of tests increases in strength were observed in all cases.

The tensile strength of a mixture of 1 part cement and 3 parts sand immersed in sodium carbonate, sodium sulphate, and sodium chlorid was decreased 0.7 per cent after 12 months and 2.7 per cent after 26 months and the compressive strength was increased 60.1 per cent after 12 months and decreased 17.2 per cent after 26 months. A similar mixture immersed in a solution of sodium chlorid, sodium sulphate, magnesium chlorid, and magnesium sulphate was considerably reduced in strength after 12 months and could be crushed between the tiagers after 26 months.

A mixture of 1 part cement to 1 part sand immersed in a solution of sodium carbonate, sedium chlorid, and sodium sulphate increased in strength in all cases except in tensile strength after 26 months. The same mixture immersed in a solution of sodium chlorid, sodium sulphate, magnesium chlorid, and magnesium sulphate experienced a decrease in strength in all cases except in tensile strength after 12 months.

Permeability tests on gravel concrete (Engin, Rec., 70 (1914), No. 13, pp. 355, 356; abs. in Indus. Engin, and Engin, Digest, 14 (1914), No. 10, p. 411).—In tests made at the University of Wisconsin to determine the permeability of concrete to water it was found that the proportions of mixture, time of mixing, sequence of placing materials in the mixer, and method of curing are vital factors when an impervious concrete is required. It was also found that permeability of lean concrete in a direction normal to the pouring is greater than in the direction of pouring.

Wooden gang mold for concrete posts, F. W. IVES (Farm. Engin., 2 (1914), No. 5, p. 85, figs. 5).—The construction and use of this mold is described and illustrated.

Recent road improvements in Hawaii, M. J. Adams (Engin. Rec., 70 (1914), No. 13, pp. 342-344, figs. 5).—This article describes road construction in territory where rainfall is excessive and where the soil is from 6 to 8 ft. in depth, overlying lava rock. After one and one-half years of service the puddled macadam surface was covered with a bituminous carpet, using two grades of asphalt and two grades of asphaltic oil. The design of culverts and bridges and the necessary road construction equipment are also described.

Harper's gasoline engine book, A. H. Verrill (New York: Harper & Bros., 1914, pp. XX+292, figs. 226; rev. in Engin. News, 72 (1914), No. 21, pp. 1045, 1046).—This book is intended for mechanics, farmers, and automobilists. It is written in popular form and takes up in turn the construction of the engine, its use at home and elsewhere, and its operation and maintenance.

Tests of substitutes for gasoline, J. A. Moyer (Power, 40 (1914), No. 16, pp. 569-572, figs. 4).—Comparative tests of kerosene, alcohol, motor spirit, and mixtures of kerosene and gasoline as substitutes for gasoline in a farm gas engine are reported, the primary object being to determine the maximum power and fuel consumption for each of the fuels used with and without water injection.

The tests showed that the maximum horsepower of the engine is considerably increased, especially with kerosene as fuel, but that the fuel consumption per horsepower-hour is considerably greater with water injection. For purposes of comparison similar tests were made with gasoline without water injection, which showed that the fuel cost per brake horsepower-hour was greater in all cases than with the other fuels. Tests with the so-called air injection devices showed that the economy of the engine is considerably improved when air is injected into the manifold.

The cause of the so-called preignition in kerosene engines, which is distinguished by sharp pounding at the connecting rod, is said to be probably not preignition at all, but is thought to be due to a "cracking" of the heavier portion of the kerosene.

Motor plowing competition of the North Kent Agricultural Association (Impl. and Mach. Rev., 39 (1913), No. 464, pp. 1089-1032; abs. in Internal. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 6, pp. 890, 801).—Results of a motor plowing competition in which four machines competed are reported. Three, four, and six furrow plows were used.

The portions of land assigned to each machine were substantially of identical character. The depth of the plowing was in all cases approximately 7 in, and the quality of the work was fair. Considering all the usual factors a 20-horse-power motor and a 3-furrow plow made the highest scores.

Standardization of farm wagons, E. E. Parsonage (Trans. Amer. Soc. Agr. Engin., 7 (1913), pp. 120-130).—The author points out the inefficiency of the present system of manufacturing and selling of farm wagons to farmers from the standpoint of their construction, and makes recommendations as to methods for bringing about standardization of wagon equipment. These are based on the standardizing and simplifying of the sizes of wagons and wheel heights and the standardizing of the track of wagons and the tire widths and thicknesses.

A cheap and effective homemade plank drag, F. G. Krauss (Hawaii Sta. Press Bul. 49 (1915), pp. 4, figs. 2).—This bulletin illustrates, describes the construction of, and gives a bill of materials for, a plank drag to be used on Hawaiian soils.

It is stated that the plank drag is most valuable when the soil breaks up "cloddy" and harrowing fails to pulverize it. "Unless the land is too moist, the plank drag should follow the harrow immediately. . . . In going over the ground with the drag a half lap should always be taken, and if necessary, the ground should be cross dragged. The drier and harder the clods the greater should be the weight applied. . . . Care should be taken not to add too much weight when the soil is moist since in so doing the soil may become compacted to an extent far greater than any beneficial results that might otherwise have accrued."

Imports and exports of agricultural machines and implements into and out of Germany in 1913 (Maschinen Zty., 12 (1914), No. 4, p. 45; abs. in Internat. Inst. Ayr. [Rome], Mo. Bul. Ayr. Intel. and Plant Diseases, 5 (1914), No. 6, p. 806).—Tabular data are given showing the exports to have been greatly in the majority excepting in the case of mowers and reapers. of which about eight times as many were imported as exported.

The manufacture of agricultural machines and implements in Russia in 1911 (Landw. Masch. u. Geräte, 14 (1914). No. 13, pp. 15-22, 40; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914). No. 6, pp. 803-805).—It is stated that this industry in Russia has developed of late years to such an extent that in 1911 it was in a position to place on the home market £6.502,400 (\$31,643,929.60) worth of machinery and implements. About \$20 factories built agricultural machinery, of which 665 were situated in European Russia, 110 in Poland, 37 in the Caucasus, and 8 in Siberia. The total output amounted in 1911 to £5.320,017, which was distributed among the various groups of machinery as follows: Tillage implements £954,530, sowing machines £804,500, harvesting machines £1.312,321, threshing machines £713,360, cleaning and grading machines £239,796, machines for preparing fodder £146,225, gins and transmissions £298,053, power motors £324,062, and other machines and implements and duplicate parts £527,170.

The consumption of agricultural machinery is said to have risen during the last 30 to 35 years from £835.840 to £12,584.870.

Methods and benefits of grading and cleaning grain, H. E. Hobton (*Trans. Amer. Soc. Agr. Engin.*, 7 (1913), pp. 41-60, figs. 4).—Attention is called to the loss to farmers due to weeds, and methods of grading and cleaning grain are described with tests.

It is shown that the cleaning machine removes the chaff, dirt, and light part of the seed, the blast machine sorts the grain according to weight, and both machines remove some of the weed seed. To remove all the weed seed the so-called trieur, which consists simply of a metal cylinder lined with cells of various depths and diameters, is necessary. The trieur separates pieces of broken grain and weed seed corresponding to the insert in use in the machine, separates grain berries according to size, and separates one grain from another.

Other machines for grading and cleaning grain described are the grain centrafugal, the snail separator, the oscillating table, the revolving cylindrical sieve, and the endless belt.

It is pointed out in conclusion that in order to secure the best seed grain the grain should be subjected to a painstaking examination with sieve, scale, and microscope.

The explosibility of grain dusts, D. J. Price and H. H. Brown (Sci. Amer. Sup., 78 (1914), No. 2031, p. 368).—The results of a cooperative study of the explosibility of grain dusts and of methods pertaining to the prevention of such explosions are reported. The following causes have been assigned to many of the explosions in milling plants in this country and abroad: (1) Use of open lights or naked flames, such as lamps, torches, gas jets, lanterns, candles, matches, etc., (2) property fires, (3) introduction of foreign material in grinding machines, (4) electric sparks from motors, fuses, switches, and lighting systems, and (5) static electricity produced by friction of pulleys and belts, grinding machines, etc. The investigation has indicated that a large number of the recent explosions and fires have been caused by the introduction of foreign material into grinding machines.

Disposal of tannery waste, A. Roth (*Jour. Amer. Leather Chem. Assoc.*, 9 (1914), No. 12, pp. 512-522).—The results of tests of different methods and equipment for the disposal of tannery wastes are reported.

A continuous-flow tank for sedimentation is said to give the best results. It should be bailled at the inlet and outlet and should have ample sedimentation and sludge capacity and good sludge-removing facilities. Sedimentation by the aid of a chemical coagulant was found to be uneconomical in such systems. The sludge was best disposed of by drying on sand beds and using as a fertilizer. The low average rate for the irrigation of tannery sewage is said to limit the use of sewage farming as a means of final disposal to very small tanneries or to tanneries where a large acreage of land is available. Intermittent sand filtration was found to be the best method of final disposal.

The design of permanent farm buildings, E. S. Fowler (*Trans. Amer. Soc. Agr. Engin.*, 7 (1913), pp. 106-117. figs. 4).—The author draws attention to the economic importance of permanent farm buildings and describes and illustrates the design of an all-concrete barn, which includes horse and cow stalls and a haymow.

Brief instructions for building a pit silo, C. Laesen (South Dakota Sta. Bul. 154 (1914), pp. 83-96, figs. 4).—This is a popular bulletin describing the construction and use of the pit silo and methods for hoisting the silage out of the pit. In four experimental pit silos no trouble was encountered from poisonous gases. Analyses of the silage from these and the college farm are reported.

RURAL ECONOMICS.

Farm costs on the Colorado Agricultural College farm, A. Keyser (Colorado Sta, Bul, 203 (1914), pp. 3-56, fig. 1).—This report outlines the system of cost accounting established for the college farm, and reports data as to the cost of farm machinery and of man and horse labor for a series of years in growing and harvesting various crops, and of the drayage, livery, carpenter work, and miscellaneous services rendered to the different departments by the college farm force as a service bureau.

Land tenure, O. R. Johnson and W. E. Foard (Missouri Sta, Bul. 12t (1914), pp. 59-110, figs. 10).—This report presents the results of a farm management survey in four townships of Johnson County, Mo., from the standpoint of land tenure.

Some of the striking points noticed were that in this locality the tenant grew more grain crops and sells a larger proportion of those grown than did the owner. He kept one animal unit for every $5\frac{1}{2}$ acres of ground, while the owner had one animal unit for every $3\frac{1}{2}$ acres. The tenant farmed more land with a given labor equipment. He got lower yields from grain crops and about the same from hay crops. His labor income was \$501, as against \$46 for the part owner and \$314 for the owner, and his family living expenses were \$354, as compared with \$413 for the owner. With the same capital the tenant made the largest labor income, the part owner ranked next, and the owner made the smallest labor income. The tenant usually put in more hours labor than did the owner and obtained a larger labor income for the same amount of work units.

The data show that 43.5 per cent of the tenants remained on the same farm two years or less. Nearly 80 per cent of the tenants moved in less than five years. Tenants living on the same farm from six to ten years made the largest labor income.

Farm owners with more than a rural school education made nearly \$600 more than those who stop with the rural school. The man with a higher education apparently remained a tenant only from one-half to one-fourth as long before becoming an owner as did those who stopped with the rural school.

[Insanity among farm people] (Bur. of the Census [U. 8.], Insane and Feeble-Minded Insts. 1910, pp. 1-179, figs. 10).—This report contains statistical data showing by States and geographic divisions the number of insane in hospitals and the number admitted in 1910. The following table shows admissions in 1910 by sex and geographic divisions:

Number of insone admitted to hospitals in 1910 per 100,000 population.

| | Urban cor | nmunity. | Rural con | amunity. |
|---|-----------------|-----------------|----------------|------------|
| Geographic divisions. | Male. | Female. | Male. | Female. |
| New England | 111. 1 90. 5 | 101. S S2. 3 | 92.7 49.9 | 91. |
| Middle Atlantic. East North Central. | 96, 1 | 72.7 | 56.9 | 49, |
| West North Central | 83.1 110.4 | 66, 1 82, 4 | 55. 0 35. 2 | 43. 31. |
| East South Central | 82.8 | 52.5 | 35.2 | 31. |
| Vest South Central | 56.9 124.2 | 55, 1 67, 3 | 28.1 44.0 | 23. 16. |
| Pacific | 95.2 | 62.8 | 53.4 | 32. |
| Total | 91.3 | 77.5 | 45.2 | 37. |

The report also shows that the rate per 100,000 population from urban communities was 73.7 for native whites, against 122.2 for foreign born and 78 for negroes. The corresponding rate for rural communities was 40 for native whites, 78.4 for foreign born, and 26.9 for negroes. The higher rate for foreign born is partially due to the large proportion of the total foreign born population being in the nature are groups.

The report indicates that 21 per cent of the insane admitted in 1910 from urban communities had general paralysis or alcoholic psychosis, whereas a similar percentage for those from rural communities was 10.4.

This report also contains a summary of the laws relating to insanity.

Institutions for insurance against sickness and accidents in rural districts (Pubs. Sec. Suisse Paysans, No. 47 (1914), pp. VII+141).—This report describes the Swiss institutions for insurance against sickness and accidents, and the principal kinds of sickness and accidents connected with agriculture as compared with other professions. A model constitution for insurance organizations is included, together with a number of statistical tables showing the frequency of accidents or sickness for various causes by ages and sex.

Farmers must be cooperators, C. O. Drayton (Greenville, Ill.: The Equily Union Publishing Co., 1914, 3. cd., pp. 188, figs. 16).—This book consists of a large number of articles relating to the principles underlying farmers' equity unions and contains a copy of the national constitution and by-laws for a local equity exchange.

Cooperative organization business methods, W. H. Kerr and G. A. Naustoll (U. S. Dept. Agr. Bul. 178 (1915), pp. 24).—Suggestions are offered as to the business methods of cooperative organizations.

According to the authors, among the essential requirements for a system of accounting records for a cooperative marketing organization are a complete set of financial records showing the business transactions and the results obtained and a record of each member's transactions with the organization. They should be capable of taking care of a maximum amount of business during the shipping season and of returning to the members the proceeds from their products within a reasonable time; should show clear pooling records when kept, so that any discrimination can be indicated quickly. There should also be auxiliary records which will give statistics and useful information for the conduct of the business. Since no two cooperative organizations are exactly alike, it is necessary that a system be devised to fit the business for which it is intended.

Every cooperative organization should have an accountant who is thoroughly familiar with the business. Every organization should keep minutes in proper form of all stockholders' or members' and directors' meetings.

The extent of depreciation should be estimated as closely as possible and provided for, and cooperative organizations should make arrangements to set aside specific amounts, or a percentage of profits, for the increase of working capital. The organization should have both an internal and external audit. Auditing circles can be effectively formed where several cooperative organizations are in the same territory.

A bibliography is appended.

[Among the egg and poultry societies of England] (Co-operation Agr. [London], 9 (1915), No. 2, pp. 25-30, figs. 6).—These pages contain a brief description of the methods of carrying on the sale and distribution of eggs and poultry by a number of local organizations.

Report of the Agricultural Organization Society, 1914 (Rpt. Agr. Organ. Soc. [London], 1914, pp. <math>IX+129).—This report outlines the aims of this society,

discusses the principal lines of work carried on and the results obtained, and gives a brief history of the branch organizations.

[Marketing of agricultural products in Queensland] (Ann. Rpt. Dept. Agr. and Slock [Queensland], 1943-14, pp. 13-19, 25-30, pls. 5).—This section calls attention to the various problems connected with the marketing of meat, frult, and dairy products, and with the development of agricultural production in Queensland.

First annual report of the bureau of farm development, 1914 (Washington Sta. Bal. 120 (1915), pp. 36, figs. 6).—This report sets forth, by counties, the results of the work for the calendar year 1914. The principal lines of extension work taken up were the control of blow soils and weeds, introduction of forage crops, successful methods of summer fallow tillage, the building up of the hog and dairy industries, the control of orchard pests, and the reclamation of tide flat lands. There were also a number of farm management demonstrations and boys' and girls' clubs formed. The text of the act establishing the bureau (E. S. R., 28, p. 900) is appended.

First annual report, department of dry land demonstration and experiment, 1914 (Washington Sta. Bul. 119 (1915), pp. 16).—This report sets forth the efforts to improve the agricultural practices in the "dry belt" of Washington. It contains a brief survey of the climatic conditions and agricultural practices and outlines the methods to be used in improving the agricultural conditions in this area. A number of field tests are to be made to determine the best methods of plowing and cultivation and the best crops to be grown. An attempt will be made to distribute trees for windbreaks, to introduce pure live stock, to improve the social and living conditions, to introduce silos, to examine soils, and to collect data regarding rainfall. (See also a previous note, E. S. R., 30, p. 497.)

Report of Missouri Country Life Conference, 1914 (Missouri Bd. Agr. Mo. Bul., 12 (1914), No. 4, pp. 138, figs. 34).—This report contains a series of addresses concerning the farmer and his family, the country schools, the country church, and other phases of the rural life movement.

The enonomic organization of England, W. J. Ashley (London: Longmans, Green, and Co., 1914, pp. VIII+213).—This book contains a series of eight lectures, among which are the English agrarian system, with the manor as starting point; the beginnings of modern farming; the break-up of the manor; and agricultural estates and English self-government.

AGRICULTURAL EDUCATION.

Important features in rural school improvement, W. T. Hodges (U. S. Bur. Ed. Bul. 599 (1914), pp. 55).—This bulletin contains extracts and summaries of reports of rural superintendents of schools as to plans for improving the schools under their supervision by means of better administration, courses of study, methods of teaching, buildings and grounds, and closer cooperation of home and school. A study of the reports from which these abstracts are taken reveals that "there is a feeling that the country child will be best educated for whatever life he may lead, whether in the city or in the country, it taught in terms of country life," and that practical subjects, such as agriculture, cooking, sewing, etc., add vitality and interest to the courses of study.

Vocational education and the State, E. DAVENPORT (School and Home Ed., 34 (1914), No. 4, pp. 131-133).—In this discussion of the separate system of vocational schools, the author outlines as some of the disadvantages the resulting stratification of society, the need of new and special teachers, and the in-

creased financial outlay. He believes that the proper goal in secondary education is the cosmopolitan high school supported by a community and subsidized both by the State and the Federal Government.

Menominee County Agricultural School and what it does, J. F. Wojta (*Hich. Farmers' Insts., Inst. Bul. 20 (1914*), pp. 321–328, figs. 3).—The author outlines the provisions of the Act of 1907 and amendments thereto under which county schools of agriculture may be established in Michigan, and gives an account of the work of the Menominee County Agricultural School.

[Agricultural education in Canada] (Agr. Gaz. Canada, 1 (1914), No. 7, pp. 519-522, 524-529, 551-558, 563, 569, 570, 593, figs. 4).—These pages include statements of the benefactions for agriculture in Canada and of the Federal appropriations; a detailed account of the buildings and equipment, instruction, etc., of Macdonald College, by F. C. Harrison; notes on school gardens in Nova Scotia and Quebec; and an article entitled Consolidation Favorable to Agricultural Education, by S. B. McCready.

Annual report of the education branch of the distribution of grants for agricultural education and research in the year 1913–14 (Bd. Agr. and Fisheries [London], Ann. Rpl. Ed. Branch, 1913–14, pp. VIII+149, pl. 1).—The form of this report has been recast in this issue, and in addition to a summary of the progress of the year chapters are devoted to descriptive notes on agricultural education and extension work in each of the 11 educational provinces of England and Wales, notes on agricultural research institutions, investigations aided by special research grants and miscellaneous grants, grants from the Development Fund paid through the board, and publications. Eight appendixes contain tabulated information concerning grants awarded for agricultural education and research in 1913–14, research scholarships in agricultural science, organization lists, other statistics, etc.

Agricultural education and research (Rpt. Bd. Agr. Scot., 2 (1913), pp. XXII-XXXII).—This is a report of progress for the year 1913 in the agricultural education and research work under the control of the board of agriculture of Scotland.

Present state of agricultural education in Germany, K. von RÜMKER (Internat. Insl. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 5, pp. 578-597).—The author gives an account of the present status of agricultural education in Prussia, including statistical data on attendance, results of examinations, and expenses of the institutions of various grades and of other types of agricultural instruction, together with a discussion of this data, and a table of similar information for the various other States of Germany.

The anniversary of the Agricultural Institute of the University of Halle, O. Ennker (Deut. Landur, Tierzuckt, 18 (1914), No. 24, pp. 282-284, figs. 3).—Notes on the development of the Agricultural Institute of the University of Halle, established 50 years ago, and a description of its equipment are given.

The inauguration of the Royal National Higher Forestry Institute (Alpe [Italy], 2. ser., 1 (1914), No. 1-2, pp. 3-27, pl. 1).—This account of the inauguration of this institute, at Florence, Italy, contains in addition to several addresses an outline of its functions and a description of the 2-year course. The institute takes the place of the Royal Forestry Institute at Vallombrosa, which has been discontinued.

Danish elementary rural schools with some reference to seminaries for the training of rural teachers, H. W. Foght (U. S. Bur. Ed. Bul. 598 (1914). pp. 45, pls. 5, flgs. 4).—This bulletin gives a detailed description of the elementary rural schools of Denmark, including their organization, management, course of study, architecture, school gardens, playgrounds, and maintenance; the office

and tenure, training, salaries, and old-age pensions of rural teachers; and a brief summary of the author's impressions, with some applications to American life.

Agriculture in elementary schools, J. P. McLennan (Ed. Gaz, and Teachers' Aid, 1914, June 29, Sup., pp. 19, figs. 6).—The author outlines work in agriculture for elementary schools in Victoria, Australia, including theoretical instruction and laboratory and plat experiments in soils, plants, crops, and forestry. Appendixes relate to work suitable for dairying, fruit growing, wheat growing, and irrigation districts, raising trees from seed at state schools, and the vegetable garden.

[Reading courses in agriculture and home economics] (Cornell Reading Courses, 2 (1913), Nos. 40, pp. 145-156, figs. 6; 42, pp. 157-184, figs. 6; 44, pp. 185-200, figs. 10; 46, pp. 201-219, figs. 7; 48, pp. 221-240, figs. 11; 3 (1913), Nos. 50, pp. 1-28, figs. 18; 52, pp. 29-44, figs. 8; 53, pp. 73-84, figs. 2; 3 (1914), Nos. 57, pp. 105-146, fig. 1; 59, pp. 149-187, figs. 27; 60, pp. 117-131, pls. 4, fig. 1; 61. pp. 189-204, pl. 1, figs. 21; 62, pp. 133-164, figs. 4; 63, pp. 205-212, figs. 3; 64. pp. 165-212, figs. 33; 65, pp. 213-254, figs. 30; 66, pp. 213-228, figs. 8; 67, pp. 257-264, figs. 3: 68, pp. 229-248, figs. 13: 69, pp. 265-284, figs. 6: 70, pp. 249-271, figs. 11; 71, pp. 285–295, figs. 9; 72, pp. 273–291, figs. 14).—These bulletins offer instruction in the following subjects: County, town, and village forests; tilth and tillage of the soil; methods of breeding oats; feeding and care of the horse; culture of the cherry; nature, effects, and maintenance of humus in the soil; culture of the blackberry; the Christmas festival; a syllabus of lessons for extension schools in home economics; sewage disposal for country homes; farm butter making; attic dust and treasures; methods of determining the value of timber in the farm woodlot; the young woman on the farm; the rural school and the community; farmhouse amusements for girls and boys; meadows in New York; canning clubs in New York State—organization, principles, and methods of canning, and canning equipment; improving the potato crop by selection; soil moisture and crop production; and culture of the grape.

Finding time for agriculture, G. M. Wilson (*lowa Agr.*, 15 (1914), No. 4, pp. 242-244).—In this article the author illustrates, taking arithmetic and spelling as examples, how time may be saved for instruction in agriculture, home economics, and manual training, by omitting useless or obsolete material in other subjects.

Methods of instruction in soils in the high-school curriculum, H. Bode (Kühn Arch., 5 (1914), pp. 423-450).—The author discusses methods of instruction in soils as a fundamental principle in (1) soil cultivation and plant food and (2) land valuation in the higher agricultural education institutions of Germany, and suggests an outline of subject matter for the winter and summer semesters.

MISCELLANEOUS.

Annual Reports of the Department of Agriculture, 1914 (U. 8. Dept. Agr. Rpts. 1914, pp. V+359).—This contains the reports of the Secretary and heads of bureaus and other administrative officers. The various reports are also issued as separates.

Twenty-seventh Annual Report of Alabama College Station, 1914 (Alabama Col. Sta. Rpt. 1914, pp. 38).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, and reports of the director and heads of departments on the work and publications of the station during the year. The report of the veterinarian is abstracted on page 783 of this issue.

Annual report of the director for the fiscal year ending June 30, 1914 (Detaware Sta. Bul. 107 (1915), pp. 15).—This contains the organization list and the report of the director on the work and publications of the station. It includes a financial statement for the fiscal year ended June 30, 1914.

Annual Report of Guam Station, 1914 (Guam Sta. Rpt. 1914, pp. 27, pls. 5, figs. 6).—This contains a summary of investigations by the special agent in charge, for the most part abstracted elsewhere in this issue.

Annual report of Hawaii Station, 1914 (Hawaii Sta. Rpt. 1914, pp. 73, pls. 3).—This contains the organization list, a summary by the special agent in charge as to the investigations of the year, and reports of the chemist, acting horticulturist, agronomist, enfomologist, and superintendents of the substations. The experimental work recorded in these reports is for the most part abstracted elsewhere in this issue, as is also a special article on The Composition of Hawaiian Fruits and Nuts (p. 761).

Biennial Report of Missouri State Fruit Experiment Station, 1913–14 (Missouri Fruit Sta. Rpt. 1913–14, pp. 32, pls. 6).—This contains the organization list, a brief report of the director for the biennium ended December 31, 1914, and reports of the entomologist and pathologist abstracted elsewhere in this issue.

Director's report for 1914, W. H. Jordan (New York State Sta, Bul. 393 (1914), pp. 627-657).—This contains the organization list and a review of the work and publications of the station during the year.

Thirty-third Annual Report of Ohio Station, 1914 (Ohio Sta, Bul. 278 (1914), pp. XXV, pl. 1).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1914, and a report of the director summarizing the work and publications of the station during the year.

Twenty-fourth Annual Report of Washington Station, 1914 (Washington Sta. Bul. 118 (1914), pp. 45, figs. 13).—This contains the organization list, a report of the work and publications of the station during the year, and a financial statement for the fiscal year ended June 30, 1914. The experimental work reported is for the most part abstracted elsewhere in this issue.

Report of West Virginia Station, 1913 and 1914 (West Virginia Sta. Rpt. 1913-14, pp. 47, pls. 6, fly. 1).—This contains the organization list; a report of the director on the work, publications, and needs of the station; and a financial statement for the fiscal years ended June 30, 1913, and June 30, 1914.

Twenty-fourth Annual Report of Wyoming Station, 1914 (Wyoming Sta. Rpt. 1914, pp. 119-194, figs. 11).—This contains the organization list; a financial statement for the fiscal year ended June 30, 1914; reports of the director and heads of departments, the experimental work recorded being for the most part abstracted elsewhere in this issue; meteorological observations noted on page 717 of this issue; an article entitled The Transmission of Swamp Fever, by J. W. Scott, abstracted on page 754 of this issue; and a reprint of a press bulletin on Plant Enemies.

Appropriations asked for the main station and substations, biennium 1915–16, 1916–17 (*Texas Sta. Circ. 5, n. ser.* (1915), pp. 32, figs. 3).—Estimates for state appropriations are presented and discussed in detail.

Press Bulletins (Ohio Sta. Bul. 278 (1914), pp. 407, 408).—Reprints of press bulletins on the ox-warble fly and dipping tick-infested sheep.

Preparation of articles for the Journal of Agricultural Research (Washington: U. S. Dept. Agr., 1914, pp. 8).—This outlines the general procedure followed in the selection of manuscripts for the Journal, and the rules for their preparation.

NOTES.

Florida Station.—A state plant act was signed by the governor April 30. It carries an appropriation of \$195,000 for the ensuing biennium, of which \$125,000 is to be used for citrus canker eradication. The state board of control having charge of the institutions for higher education in Florida has been designated as the plant board to carry out the provisions of the act. It is proposed to organize the work under departments of citrus canker eradication, plant pathology, insect pests, and nursery inspection. The board is given authority to cooperate with this Department, the State Department of Agriculture, the station, and other agricultural agencies.

Idaho University and Station.—Plans for a building to house the department of farm engineering has been approved, and the building will be erected during the summer. Extensive improvements to Morrill Hall will also be made to increase the facilities of the departments of farm crops and horticulture. The new work of the station includes animal nutrition investigations and experiments with silage from crops not as yet commonly grown in the Northwest for silage purposes. Both projects are to be carried on cooperatively by the departments of animal husbandry and chemistry.

E. P. Taylor has resigned as field horticulturist to engage in private work in Utah. G. J. Downing, assistant horticulturist, has been detailed to take active charge of the project formerly in his charge on the determination of the water requirements of apple crops and the effect of varying amounts of irrigation water on the keeping properties of apples. T. H. Parks has resigned as field entomologist to engage in private work. H. P. Fishburn, assistant professor of agricultural chemistry, has been granted a year's leave of absence for graduate work at the University of Chicago. Frank Lafrenz of the class of 1915 will become superintendent of the Sandpoint substation in June.

Minnesota University.—Twenty-six courses in agriculture and home economics are announced for the summer session of the college of agriculture.

Missouri University and Station.—The department of farm management will conduct a farm survey in several parts of the State during the coming summer.

R. H. Besse has resigned as assistant to the state leader of farm advisers to become state leader of county agents for Wyoming. T. J. Talbert, extension entomologist at the Kansas College, has been appointed extension assistant professor of entomology, Miss Carrie L. Pencost, extension instructor in home economics, and A. H. Hollinger, now assistant in entomology, deputy inspector of nurseries.

Montana College and Station.—Leo Faust has been appointed to the state board of education vice O. W. McConnell. C. N. Arnett, professor of animal busbandry in the Iowa College, has been appointed head of the animal husbandry department beginning soon after June 1.

New Jersey College and Station.—Irving L. Owen, associate agronomist in the station and manager of the college farm, has resigned to become county farm demonstrator for Middlesex County and has been succeeded by Charles S. Van Nuis. Miss Marion T. Pleasants, laboratory assistant in botany, and

Willis H. Pearson, assistant chemist, have resigned. Miss Fannie F. Cooper has been appointed assistant in extension work in home economics, and W. Raymond Stone orchard foreman.

North Carolina Station.—C. W. Mitchell, of Aulander, has succeeded K. W. Barnes as a member of the governing board of the station.

North Dakota College and Station.—The recent legislature passed an act which provides for a board of regents to have charge of all of the higher institutions of learning in the State, including the normal schools. Recent appointees to the board of trustees of the college and station include Walter Reed of Amenia, F. Kindred of Hillsboro, and August Hanson of Fargo.

Ohio State University and Station.—Arrangements have now been completed with eight other colleges of the State for the five-year combination arts-agricultural course (E. S. R., 30, p. 397), and several other institutions have the plan under consideration.

A bill is pending in the legislature for the establishment of a branch experiment station on the university farm with the dean of the college of agriculture as associate director. The bill provides for experimental work in connection with the courses given by the different departments, duplication of the station work at Wooster being avoided. The expenses of the substation would be defrayed from the university funds.

Dean H. C. Price of the college of agriculture has resigned, effective July 1. George Livingston, assistant professor of agronomy since 1911, has resigned to become specialist in grain marketing in the Office of Markets of this Department.

Oklahoma Station.—Recent appointments include A. G. Weigel, assistant chemist at the Massachusetts Station as assistant chemist, effective March 1, and D. Glen Morgan as assistant chemist in the feed and fertilizer division.

Pennsylvania Institute of Animal Nutrition.—J. W. Park, assistant in animal nutrition since 1912, has resigned to accept a position with the Office of Markets of this Department.

Virginia Station.—Dr. H. S. Reed, plant pathologist and bacteriologist since 1908, has resigned to accept a similar position at the Citrus Station at Riverside, Cal., and has been succeeded by Dr. F. D. Fromme, assistant botanist at the Indiana Station.

Virginia Truck Station.—II. II. Zimmerly, instructor in horticulture in the Pennsylvania College, has been appointed assistant horticulturist beginning June 1. J. A. McClintock has been appointed assistant plant pathologist beginning June 15.

Seventh Graduate School of Agriculture.—The next session of the Graduate School of Agriculture, under the auspices of the Association of the American Agricultural Colleges and Experiment Stations, will be held at the Massachusetts Agricultural College, Amherst, Mass., in July, 1916. The headquarters of the school will be in the large agricultural building which is now being erected on the campus.

Agricultural Education at The Scuthern Conference for Education and Industry.—The Southern Conference for Education and Industry, organized by the merging of the forces represented by the Southern Educational Association and The Conference for Education in the South, held a 4-day meeting at Chattanooga, Tenn., beginning April 27.

The departments and special conferences of the preceding organizations were organized into a small number of working bodies, such as committees of the Southern Educational Council, and community, agricultural education, grain growers', and live stock, fruit growers', bee culture, marketing, artisans', college, teachers', country church, and teacher training conferences.

NOTES, 799

At a joint conference of the college representatives, superintendents, and teachers, home work with school credit was discussed. The leader of this joint conference, J. F. Marsh, of West Virginia, submitted a general home-project plan aiming to give outside activities sufficient cultural value to warrant school credit and thus bring about a closer relation between the home and the school. The plan set forth methods for using the home, the garden, the farm, the shep, and the factory as laboratories, thus making the school a factor in community progress.

The Southern Educational Council considered (1) what the school is, and (2) what it shall undertake. Under these general propositions one of the topics considered was what should be the relation of the country teacher to the home and extension work in agriculture and home making. Among the topics considered by the teachers' conference may be mentioned a plan for making the club an integral part of the work of both town and country schools, including (1) a boys' corn club. (2) a girls' gardening club. (3) an arts and crafts club, with related exercises in reading, writing, drawing, etc.

The theme for discussion at the college conference was The Readjustment of Ideals, Courses, and Methods to Develop Leaders. In discussing The Relation of the College Curriculum to Human Life and Work, Dr. A. C. True, of this Office, said among other things:

"In a general way agriculture, mechanic arts, commerce, and the household arts are the general terms under which the industries may be grouped. In the elementary school the child can easily be brought into contact with materials and principles dealt with in the industrial world through simple objective instruction in nature study, elementary agriculture, wood and metal working, cooking, sewing, playing at store-keeping, etc. In the secondary school he can go further in the technique and principles of the more fundamental arts. In the college he should learn something of the great diversity of the industries, the opportunities they offer for the application of scientific principles and for original research, their relations to each other and to the professions and fine arts, and the economic, sociological, ethical, governmental and other factors involved in their proper development, or in general their true place and functions in the body politic.

"In such studies agriculture, the most fundamental of the arts and much more comprehensive in its range of activities and relations than most people think, may well have a prominent place. The narrow way in which most college men, including those brought up on farms, think and speak about agriculture is to me very interesting and deplorable. It seems to mean to them merely the raising of a few crops, e. g., corn, hay or beans, or a few animals, e. g., pigs or cows. They seem never to have considered the wide range of even American agriculture, the many sciences to which it is closely related, the great economic, governmental, and sociological interests involved in the development of our agriculture and our rural communities. Or if they have incidentally thought of some of these things they have little appreciation of their real importance and significance. And this narrowness of outlook of college men pertains also to other industries."

Necrology.—Elisha Wilson Morse, editor of the sections of animal production and dairying of *Experiment Station Record* from 1908–1913, and subsequently engaged in editorial work in the Dairy Division of this Department, died at Washington, D. C., April 18. Professor Morse was born at Brockton, Mass., April 20, 1866, and attended the Massachusetts Agricultural College for a short time. He was graduated from the Bussey Institution of Harvard University in 1897, and remained there until 1908 as instructor in natural history,

teaching a wide range of subjects but especially animal husbandry and dairying.

In his various activities he acquired an unusual acquaintance with the literature of these subjects, particularly as regards animal nutrition and genetics and the history of domestic animals. He gave a course of lectures at the fourth and fifth Graduate Schools of Agriculture, and his preliminary studies as to the ancestry of domesticated cattle, in which he had become a recognized authority, were published in the report of the Bureau of Animal Industry for 1910 (E. S. R., 27, p. 172).

Henry E. Van Deman, well known for his writings and other activities in pomology, died at Washington, D. C., April 28. Professor Van Deman was the first professor of horticulture at the Kansas College and the first head of the division of pomology of this Department. He resigned in 1893 to take up horticultural, editorial, and other work and has been a contributor to many periodicals and has served as a judge of exhibitions of fruit in nearly every State.

The death in the European War on November 3, 1914, is reported of Otto Maurer, associated about 1911 with the bacteriological studies on eggs at the Kansas Station. He was educated in Germany and the University of Wisconsin and was 26 years of age.

Charles II. Martin, who had been working in collaboration with the Rothamsted Experimental Station on soil protozoa, and had published several contributions on the subject and on the cecal parasites of fowls, was killed in the European War May 3.

Miscellaneous.—The Ohio Agricultural Commission was abolished by the recent legislature, being succeeded by a state board of agriculture of 10 members appointed by the governor to serve without compensation and with an executive secretary. All of the powers of the commission will devolve upon the board except the control of the Ohio Station, for which a separate body is provided, and the agricultural extension work, including farmers' institutes, which is placed in the charge of the Ohio State University.

Breeder's Gazette notes that W. G. Scholtz has been appointed director of farm markets in Idaho under a new law effective May S. His duty will be to cooperate with producers and consumers in plans of distribution, to investigate alleged frauds in the sale of real estate to homeseekers, regulate advertising pertaining to colonization, maintain a farm labor employment bureau and lists of farm property for sale for the use of prospective buyers, and otherwise improve farm life conditions.

CONTENTS OF VOL. XXXII, NO. 9.

| Recent work in agricultural science. SUBJECT LIST OF ABSTRACTS. AGRICULTURAL CHEMISTRY—AGROTECHNY. Yearbook of chemistry, edited by Meyer. The hydrogen ion concentration, Michaelis. The glycerids of fats and oils, IV-VIII, Bömer et al. Linseed mucilage, Neville. The amount of water-soluble carbohydrates in flaxseed, Van Kampen. Studies on enzym action, XII, Falk and Sugiura. The thermoregeneration of sucrase, Bertrand and Rosenblatt. Relationship between the protein substances of yeast and sucrase, Thomas. Soy bean urease.—Effect of dilution, acids, alkalis, and alcohol, Marshall, Jr. The mode of action of urease, Van Slyke, Zacharias, and Cullen. Preparation of "neutral" ammonium citrate, Eastman and Hildebrand. Cause of error in precipitation of ammonium-magnesium phosphate, Quartaroli. Determination of phosphorus in fertilizers and feeds, Dusserre and Chavan. The estimation of phosphates in soil extracts, Prescott. Determination of carbon in soils and soil extracts, Ames and Gaither. | |

VEDEN.

II CONTENTS.

| | rage. |
|--|-------|
| Quantitative estimation of the salt-soluble proteins in wheat flour, Olson | 808 |
| An investigation of the presence of furfurol in cider vinegar, Anderson | |
| An investigation of the presence of furnition in close vinegal, Anderson. | 808 |
| Analysis of maple products.—111, Range of variation in strups, Snell and Scott | 808 |
| The reductase (fermentation reductase) test, Dons | 809 |
| Manufacture and use of unfermented grape juice, Husmann | 809 |
| Some abnormal factors of so-called farmers' cider vinegars, Diggs | -809 |
| Hop investigations | 809 |
| | |
| METEOROLOGY. | |
| | |
| Report of the chief of the Weather Bureau, 1914 | 810 |
| Monthly Weather Review | 810 |
| Why some winters are warm and others cold in east United States, Humphreys | 811 |
| Predicting minimum temperatures for frost protection, Smith | 811 |
| Climate and meteorology of Australia, Hunt | 811 |
| t finate and increorology of Australia, Indic. | 011 |
| SOILS—FERTILIZERS. | |
| SOILS—FERTILIZERS. | |
| Soil erosion in the South, Davis | 811 |
| Boll Closion III (He) outly golds Doso | |
| Analysis of Florida muck soils, Rose | 811 |
| Geography of the soils of Georgia, Merrill. | 811 |
| Composition of the soils of the different glacial drift sheets, Alway | 812 |
| Soil survey of Orange County, New York, Crabb and Morrison | 812 |
| Soil analysis | 812 |
| Soil analysis | 812 |
| Studies of an acid soil in Assam, Meggitt | 812 |
| The colloid chemistry of humus, Odén | 813 |
| Soil colloids and the soil solution, Cameron. | 813 |
| Soil water in relation to plant growth, Colebatch | 813 |
| Effects of variations in moisture content on soil and wheat, Harris. | |
| Effects of variations in most tire content on son and wheat, Hairis | 814 |
| The evaporation of water from soil, Keen | 815 |
| Partial sterilization of soil by volatile and nonvolatile antiseptics, Buddin | 816 |
| Increased nitrate content of a soil subjected to temporary drying, Buddin | 817 |
| Ammonification studies with soil fungi, McLean and Wilson | 817 |
| A contribution on the nitrogen problem, Scheerlinck | 818 |
| Soil bacteriological investigations | 818 |
| [Soil inoculation] | 818 |
| The results of some experiments with farmyard manure, Berry | 818 |
| Results of two years' work on London Soil Experiment Field, Roberts | 819 |
| Peat moors with special reference to the air-nitrogen question, Benetsch | 820 |
| The utilization of part in Italy, Degi | |
| The utilization of peat in Italy, Rossi. German and other sources of potash supply, Macdowell | 820 |
| German and other sources of potasi supply, Maddowell | 820 |
| Investigation of sources of potash in Texas, Phillips | 820 |
| Potash from kelp, Cameron | 821 |
| Potash from kelp, Cameron. Radium as a fertilizer, Hopkins and Sachs. | 821 |
| Fertilizer inspection. | 822 |
| - | |
| AGRICULTURAL BOTANY. | |
| | |
| Plant breeding, Bailey and Gilbert. Enothera grandiflora of the herbarium of Lamarck, De Vrics. | 822 |
| Enothera grandiflora of the herbarium of Lamarck, De Vrics | 822 |
| Experimental variations in Tricholoma nudum, Matruchot | 822 |
| The presence of Orobanche minor on Pelargonium zonale, Scheerlinck | 822 |
| Parasitic specialization, Heske | 822 |
| Carastic specialization, Heske | |
| Chondriosomes in fungi, Janssens | 822 |
| Morphology of the barley grain, Mann and Harlan. | 823 |
| Direct absorption and assimilation of carbohydrates by green plants, Knudson. | 823 |
| The chlorophyll compounds of the peach leaf, Reed and Stahl | 823 |
| Studies on lycopin and its relations with chlorophyll, Lubimenko | 824 |
| Absorption and excretion of electrolytes by Lupinus albus, True and Bartlett. | 824 |
| Absorption and excretion of electrolytes by Lupinus albus, True and Bartlett. | 824 |
| The process of anthocyanin pigment formation, Combes | 824 |
| Relation of transpiration to the composition of white pine seedlings, Burns | 824 |
| Function of water reserves, du Sablon. | 825 |
| The translocation of materials in aging leaves, Swart | 825 |
| | 825 |
| Anatomical structure of roots under abnormal tension, Jaccard | |
| Effects of compression on root structure, Molliard | 825 |

| | Page |
|---|--------------|
| Deformation of heath on the seashore, Devaux | 82 |
| Monstrosities of germination in cauliflower and cabbage, Dubard and Urbain | 825 |
| Injury to vegetation by coal tar and other vapors, Ewert. | 826 |
| Studies on smoke injury to vegetation in Ratibor-Plania, Otto | 826 |
| The vegetation of south Florida, Harshberger. | 826 826 |
| The regentation of routin 1 totalia, flation octget | 02 |
| FIELD CROPS. | |
| Forage plants and their culture, Piper. | 827 |
| Report of department of agronomy | 827 |
| The physical characteristics of soils and their grain-producing power, Stempel | 827 |
| Fertilizers and the production of cereals, Palladius | 827 |
| The small grains in Tennessee, Mooers | 827 |
| Turf, Hutchinson. Grading and baling Philippine fibers, Edwards. | 828 |
| Description of the standard grades of abacá (Manila hemp), Salecby | 828 828 |
| The rejuvenation of depleted abacá fields, Nickles. | 828 |
| Alfalfa farming in America, Wing. | 828 |
| Alfalfa farming in America, Wing | 828 |
| Alfalfa, Clarke | 828 |
| Fertilizer experiments with beans in the valley of Mexico, Calvino | 828 |
| Bur clover seed; means of hastening their germination, Duggar and Tisdale Anatomical coefficients of maize, its height and nitrogen content, Moskvichev. | $829 \\ 829$ |
| Effect of the submersion of corn, Marchettano. | 829 |
| Fertilizer experiments with maize, Calvino | 829 |
| The modern cultivation of corn, Dominguez | 829 |
| Cotton cultivation in the West Indies, Nowell and Ballou | 829 |
| Cotton experiments], Macdonald | 829 |
| Influence of some chemical reagents on sprouting of potato tubers, Nicklisch. | $829 \\ 829$ |
| Group classification and varietal descriptions of American potatoes, Stuart | 830 |
| Improvement of the seed potato, Martinet. | 830 |
| Utilization of potatoes in Europe, Skinner | 830 |
| On the pollination and crossing of rice, Ikeno | 830 |
| The correlative relations of the internodes of a stalk, Plahn-Appiani | 830 830 |
| Soy beans], Gill. Spacing experiments in sugar beet cultivation in Hungary in 1913, von Janesó. | 830 |
| Drilling fertilizer experiments with sugar beets in Hungary in 1913, Gyárfás | 830 |
| Seedling canes and manurial experiments, d'Albuquerque and Bovell | 831 |
| Fertilizer on sugar cane], Easterby | 831 |
| Experiments and observations on Helianthus annuus, Satsyperov | 831 |
| Sweet clover, CunninghamSweet clover, Cook | 831 831 |
| Deli tobacco, a mixture of races, based on differences in leaf-breadth, Honing. | 831 |
| Experiments on the manuring of turnips in 1909, 1910, and 1911, Wyllie | 832 |
| Correlation and variability relations in wheat, Oetken | 832 |
| The flowering and pollination of some forms of spring wheat, Shitkowa | 832 |
| Spacing, depth of seeding, and tillering in spring wheat, Rabomnova | 832 833 |
| Vashington wheats, Schafer and Gaines | 833 |
| Nitrogen content of the wheats of southeastern Russia, Tuliakov | 833 |
| A new sterilization stopper and method of storing seeds, Plaut | 833 |
| Seed inspection. | 833 |
| Forty years of seed control work, Heinrich | 833 |
| Veeds of barley fields in the forest area of European Russia, Maltsey | 833 833 |
| todas de santo, notas en ano estos aron de paropolar, estadas, estados, estados, estados en ano | 000 |
| HORTICULTURE. | |
| How to send living plant material to America, Fairchild | 833 |
| The use of hotbeds and cold frames on the farm, Dacy | 834 |
| The farmer's vegetable garden, Werner. | 834 |
| nheritance and selection by vegetative propagation of garlic, Vogler | 834 |
| Orchard and garden spraying, Crane | 834 834 |
| Report on the section of fruit breeding. | 834 |

| · | Page. |

Abstract Number.

No. 9.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY-AGROTECHNY.

Yearbook of chemistry, edited by R. Meyer (Jahrb. Chem., 23 (1913), pp. XII+642).—A retrospect of the more important progress made in the realm of pure and applied chemistry during 1913, including among others sections on Physical Chemistry, by H. Freundlich; Inorganic Chemistry, by K. A. Hofmann; Organic Chemistry, by E. Hjelt; Physiological Chemistry, by P. Rona; Pharmaceutical Chemistry, by H. Beckurts; Chemistry of Foods and Condiments, by H. Beckurts; Agricultural Chemistry, by A. Morgen and C. Beger; Technology of Sugars, by A. Herzfeld and K. Zablinsky; The Fermentation Industry and Starch Manufacture, by M. Delbrück and O. Mohr; Fats, Waxes, and Mineral Oils, by D. Holde; and Tanning, by M. Nierenstein.

The hydrogen ion concentration, L. MICHAELIS (Die Wasserstoffionen-Konzentration. Berlin: Julius Springer, 1914, pp. XIII+210, figs. 41).—This deals with the significance of the hydrogen ion concentration for biology and sets forth in detail the methods of measuring it. It is divided into three parts, namely, theoretical significance of the hydrogen figure, the hydrogen figure of various fluids in the living organism, and the measuring of the hydrogen figure.

The volume is the first of a series of monographs intended to cover the field of plant and animal physiology. It is issued by M. Gildemeister, E. Godlewski, C. Neuberg, F. Czapek, and J. Parnas, and edited by the two last named.

Contribution to our knowledge of the glycerids of fats and oils.—IV-VIII, A. Bömer et al. (Ztschr. Untersuch. Nahr. u. Genussmtl., 25 (1913), No. 6, pp. 321–386, figs. 2; 26 (1913), No. 10, pp. 569–618, figs. 10; 27 (1914), No. 1–3, pp. 153–172, figs. 2).—By repeated fractional solution in ether, pure glycerids of saturated fatty acids were obtained from lard. Tristearin, present in beef and mutton fat, was absent in lard. The insoluble glycerid of lard is not heptadecyldistearin as believed by Kreis and Hafner (E. S. R., 16, p. 332) but is a palmityldistearin. It differs in its melting point and crystalline structure from the palmityldistearin noted in mutton tallow, and in all probability exists in the two as the α and β forms.

Lard also contains a dipalmitylstearin but whether this is identical or isomeric with a stearyldipalmitin present in mutton tallow could not be established. The melting point of stearyldipalmitin and α -palmityldistearin was not affected by melting the crystals. In the lards examined the amount of stearyldipalmitin was about 2 per cent and of α -palmityldistearin about 3 per cent.

In the preparation of α -distearly from α -dichlorhydrin and potassium stearate a large amount of tristearly was produced at the same time. The melting point of the α -distearly was 77.8° C. (corrected, 78.5°), but a double melting point could not be noted.

In the synthetic preparation of β -pulmityldistearin from α -distearin and palmitic acid appreciable amounts of tristearin were formed and apparently also some stearyldipalmitin. Synthetic β -palmityldistearin melted in the neighborhood of 63°, and in this regard and in its crystallization from ether and the form of its crystals it resembled the palmityldistearin from mutton tallow. The compound present in mutton tallow is probably the β combination.

The Polenske number is deemed suitable only for determining the grosser adulteration of lard with beef or mutton tallow. The quality of the reaction is not increased by previously crystallizing the fat from solvents. In many cases as much as 20 per cent of tallow can not be noted with it in lard, and the authors' method, which depends on the difference in the melting point of glycerids and the fatty acids of lard and tallow (beef, mutton, and press) is preferred. This method is described with much detail. Leys' (E. S. R., 19, p. 611) and Emery's (E. S. R., 20, p. 11) methods did not furnish satisfactory results. The authors believe that in order to obtain satisfactory results the saturated fatty acids must be prepared in a more or less pure state, or, to say the least, more definite characteristics of the respective glycerids must be determined.

The authors' method has been studied with mixtures of lard, beef tallow, and plant oils (coconut, peanut, sesame, and cotton-seed oils), hardened oils (E. S. R., 28, p. 616), mixtures of hardened oils and lard, so-called abnormal lards, mixtures of butter and lard, and lard and goose fat. The so-called abnormal lards were from animals fed on corn, eoconut cake, cotton-seed meal, and sesame-seed meal. In none of the fats of these animals were there any signs present such as indicated by the new melting point difference method of the difficultly soluble glycerids and their fatty acids which might make it appear as though beef tallow were added.

Linseed mucilage, A. Neville (Jour. Agr. Sci. [England], 5 (1913), No. 2, pp. 113–128).—The vegetable mucilages have been only sparingly studied. These experiments show that linseed mucilage is a substance of carbohydrate nature, having all the characteristics of hydrated cellulose, and that the term "mucocellulose" given to it by Cross and Bevan is well chosen. On hydrolysis it yields both hexose and pentose sugars and practically nothing else. It is considered very doubtful whether the other products obtained in hydrolyzing an average sample are decomposition products, or, at any rate, direct decomposition products of pure mucilage. The experimental results draw attention once more to the use of the term "soluble carbohydrates" in connection with feeding stuffs. In the usual routine analysis of feeds many different compounds are grouped under this heading and are necessarily assigned one feeding value.

The amount of water-soluble carbohydrates in flaxseed, G. R. Van Kampen (Landw. Vers. Stat., 83 (1914), No. 5-6, pp. 471-476).—The sugar content of flaxseed and linseed cake was determined. The amounts found in the seeds varied from 2 to 2.5 per cent and the cake coming therefrom contained about 3 to 4 per cent. The sugar may come from either the glucosids or mucilage present in the seed but only glucose could be detected. Sugar could be detected in the flaxseed coat with copper sulphate and potassium hydroxid. On heating a section of the seed a precipitation of cuprous oxid was very noticeable. The deposition of copper oxid was found to be of less degree in the parenchymatous and sclerenchymatous cells and absent in the innermost parts of the endosperm and the cotyledon. From the fact that the greater part of the sugar is found in the seed coat and is lost through germination, it is concluded that it does

not serve as a reserve material. The results also have a direct practical bearing in determining whether a molasses feed with a linseed base has added sugar or not.

A reaction for protein was given in the cotyledons, and it was very definite in the alcurone grains.

Studies on enzym action.—XII, The esterase and lipase of castor beans, K. G. Falk and K. Sugiura (Jour. Amer. Chem. Soc., 37 (1915), No. 1, pp. 217-230).—The results regarding extraction, described in the paper previously reported (E. S. R., 31, p. 711), were confirmed with a new castor bean preparation.

"The action of the castor bean preparation on triacetin in the presence of some neutral salts is described. The activity of the preparation was tested after drying and heating under different conditions. An esterase preparation, active toward ethyl butyrate, was separated by extraction with water, and its properties studied in solution and in the solid form. Its probable identity with glycero-phosphatase was suggested. A lipase preparation, active toward triacetin, was separated by extraction with 1.5 normal sodium chlorid solution, and its properties studied. The forms of combination of the nitrogen in the preparations are determined. The probable protein nature of the esterase and lipase is discussed."

The thermoregeneration of sucrase, G. Bertrand and M. Rosenblatt (Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 20, pp. 1455-1458; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, I, pp. 909, 910).—This is a study of the hydrolyzing properties of invertase, prepared from yeast by different processes, after exposure to varying temperatures.

A maceration of dried yeast heated at 70 or 80° C. for one minute loses all its hydrolyzing power, whereas if heated at 90 or 100° for one minute it regains a large part of its hydrolyzing power. "A sample of fresh baker's yeast, ground with sand and water, does not show this regeneration of hydrolyzing power at the higher temperature. Successive treatment of this yeast with alcohol and ether yields a powder which shows no sign of regeneration, whereas two successive treatments with acetone, followed by rapid filtration and dehydration, give an invertase which exhibits the above phenomenon of thermoregeneration. A sample of the yeast which has undergone autolysis for from one to two days or even four days, when putrefaction has set in, yields, by subsequent maceration with water, a solution of invertase which shows very marked regeneration when heated to 90 or 100° for one minute, whilst being almost inactive after heating to 70 or 80° for the same time."

The relationship between the protein substances of yeast and sucrase, P. Thomas (Compt. Rend. Acad. Sci. [Paris], 158 (1914), No. 22, pp. 1597-1600; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 621, I, p. 909).—Cerevisin, obtained from yeast after contact with water, was found to hydrolyze sucrose. This hydrolyzing power increased with the fineness of the powder and the temperature used in maceration. Similar phenomena were not noted with the proteins obtained in a coagulated condition from yeast, and invertase therefore is apparently formed from cerevisin through the agency of water. The hydrolyzing powers of cerevisin were greater with autolyzed than with fresh yeast. This is of interest in connection with Bertrand and Rosenblatt's work on the thermoregeneration of intervase, noted above.

On soy bean urease.—The effect of dilution, acids, alkalis, and ethyl alcohol, E. K. Marshall, Jr. (Jour. Biol. Chem., 17 (1914), No. 3, pp. 351-361).—By this work it is shown that the hydrolysis of urea by urease is practically proportional to the enzym concentration. The velocity increases with dilution to a maximum, and with further dilution decreases slightly. "The

velocity of the hydrolysis is independent of the hydrogen or hydroxyl lon concentration within rather narrow limits. Hydrochloric acid or sodium hydroxid in sufficient amounts inhibits the action of the enzym and also destroys it. Ethyl alcohol exercises only a moderate inhibitory effect, and its destructive action is apparently very slight."

The mode of action of urease, D. D. VAN SLYKE, G. ZACHARIAS, and G. E. Cullen (Abs. in Proc. Soc. Expt. Biol. and Med., 11 (1914), No. 5, p. 155).—The alkalinity of the ammonium carbonate generated during the process accounts for the retardation of urease activity.

"When the solution is kept neutral by a proper phosphate mixture the products have no effect on the velocity of the reaction. Elimination of the effect of the products makes arease a particularly favorable enzym with which to study the reaction between enzym and substrat. The results indicate that the action consists of two successive reactions; combination of enzym and substrat in definite proportions; and decomposition of the compound, the urea being thrown off as ammonium carbonate; each of the two reactions consuming a definite portion of the total time. Formulation of these relations leads to

the equation $t = \frac{I}{c} \log \frac{a}{a-x} + \frac{x}{d}$, t representing the time required for the decom-

position of x amount of the initial substrat amount, a; c is a constant representing the velocity of combination of enzym and substrat, d representing the velocity of decomposition of the complex. The values of c and d can be determined independently, and one can thereby determine whether changes in conditions affect the combination reaction or that of decomposition. Neutral salts retard the combination. Alkaline reaction hastens it, but retards the decomposition. Slightly acid reaction greatly retards the combination, affecting the other reaction but little. The independent variation of the two phases of the process of enzym action explains some previously obscure facts in regard to the effect of alkalis, acids, and other substances on enzym action."

The preparation of "neutral" ammonium citrate, E. D. EASTMAN and J. H. HILDEBRAND (Jour. Indus. and Engin. Chem., 6 (1914), No. 7, pp. 577–580, figs. 3).—Following a discussion of methods previously proposed by others for preparing neutral ammonium citrate (E. S. R., 29, pp. 203, 718), it is announced that with the aid of the hydrogen electrode an indicator method has been developed for the preparation of triammonium citrate. The hydrogen ion concentration given by a solution of this salt having a specific gravity of 1.09 is $10^{-4.4}$. "This concentration is obtained in the preparation of the citrate by the use of an easily prepared color standard, made by mixing HCl and Na₂-HPO₄ solution. The results of a simultaneous determination of the 'neutral point' with the electrode and conductivity methods are shown graphically, and there are given results of several trials of the formula suggested."

The difficulties of the fertilizer chemist in determining the available phosphoric acid do not seem to be due entirely to the lack of uniformity of ammonium citrate solution used. "It may be impossible to distinguish sharply between 'reverted' and 'available' phosphate by means of neutral ammonium citrate solution."

Cause of error in the precipitation of ammonium-magnesium phosphate in the presence of ammonium citrate, A. Quartaroli (Staz. Sper. Agr. Ital., 46 (1913), No. 5, pp. 322-328).—It is believed by some that ammonium-magnesium phosphate is not entirely insoluble in a strong solution of ammonia, and that danger also exists of the precipitation of magnesium oxycitrate. In these investigations it is shown that when either ferric chlorid or aluminic chlorid

^a Jour. Amer. Chem. Soc., 35 (1913), Nos. 7, pp. 847-871, figs. 15; 10, p. 1538.

is present the precipitation of ammonium-magnesium phosphate is somewhat inhibited.

Investigations on the determination of phosphorus in fertilizers and feeding stuffs, C. Dusserre and P. Chavan (Mitt. Lebensm. Untersuch. u. Hyg., Schweiz. Gsndhtsamt., 4 (1913), No. 4, pp. 261–267; abs. in Chem. Ztg., 37 (1913), No. 87, p. 877).—It is stated that the Pemberton method (E. S. R., 6, p. 865), when slightly modified, yields results which are comparable with the method usually used, and is rapid, inexpensive to conduct, and has other great advantages. As a result of determining the phosphorus content of meadow hay from various lots harvested in different years, it is said that of each 100 parts of phosphorus from 4 to 9 parts are present as phosphatids, 55 to 74 parts in inorganic combination and as phytin, and 21 to 40 parts as nucleoproteins. By fertilizing with phosphorus the yield and phosphorus content of the plant are increased, especially that inorganically combined and the phytin fraction. For determining phosphorus in organic substances (hay extracts) Neumann's method is recommended, but it yielded higher results than the ashing method.

The estimation of phosphates in soil extracts, J. A. Prescott (Jour. Agr. Sci. [England], 6 (1914), No. 2, pp. 111-120).—A series of experiments made with the object of determining the best conditions under which the Pemberton procedure may be used. The method finally adopted, inclusive of reagents, is as follows: Reagents—concentrated ammonium nitrate, 500 gm. of ammonium nitrate, in 1 liter of water; ammonium molybdate solution, 150 gm. ammonium molybdate dissolved in 1,000 cc. of water and poured into 1,000 cc. of nitrie acid (specific gravity 1.2); 2 per cent sodium nitrate.

"A measured volume of soil extract containing 5 to 10 mg. P_2O_5 is evaporated to dryness on a gently heated sand bath and the residue ignited at a dull red heat for 15 minutes, as in Neubauer's method. The residue is taken up with 50 cc. of 10 per cent sulphuric acid and digested for half an hour on a sand bath. The extract is diluted if necessary, filtered, and the residue washed with hot water; filtrate and washings amounted to 110 cc. This procedure is found to extract all the phosphate, when the amount of the original solution is not more than 100 cc. in the case of an HCl extract. For soil extracts containing much silica it is necessary to heat the residue from the evaporation for two hours at 120° to 160°, the silica interfering otherwise with the subsequent manipulations.

"To the solution prepared as above, 25 cc. of the concentrated ammonium nitrate is added and the mixture brought to 55°. Twenty-five cc. of the ammonium molybdate, previously brought to the same temperature, is then added and the mixture stirred, allowed to cool, and filtered after standing two hours. The supernatant liquid is decanted through a filter paper and the precipitate washed by decantation several times with a 2 per cent sodium nitrate solution; this solution prevents the deflocculation of the precipitate, which usually happens when distilled water is used alone. The washing is continued till the washings are no longer acid. The filter is then washed into the beaker with water and the precipitate dissolved in standard alkali and titrated back. For the precipitation it is found convenient to use a water bath kept at 55°, in which the beakers containing the solution are placed till they have acquired the temperature of the bath. The factor recommended for tenth-normal alkali is: 1 cc.=0.0003004 gm. P₂O₅."

Determination of carbon in soils and soil extracts, J. W. Ames and E. W. Gaither (Jour. Indus. and Engin. Chem. 6 (1914), No. 7, pp. 561-564, fig. 1).—It is pointed out that the methods of estimating total carbon in soils by oxidation with a mixture of chromic and sulphuric acids have been tested

by Warrington and Peak ^a and by Cameron and Breazeale (E. S. R., 15 p. 744) with varying results. As determinations of carbon were needed in 1 per cent hydrochloric acid and 4 per cent ammonia extracts of soils and the employment of neither the Parr calorimeter nor the combustion furnace was feasible, a thorough test of the chromic and sulphuric acid method was made and the results compared with those given by combustion with copper oxid in a furnace. In addition to this, combustions were made with alkaline permanganate solution with a concentrated chromic acid solution and continued boiling.

The soils gave figures which compare well with those yielded by ignition methods. Dilute mixtures of chromic acid and alkaline permanganate gave low results. The work seems to give conclusive proof that the concentrated chromic and sulphuric acid treatment completely decomposes organic and inorganic carbon present in soils and overcomes the objection raised by Cameron and Breazeale and Hall and Miller, b

"If boiled for 30 minutes, a mixture of 3.3 gm. of chromic acid in 10 cc. of water to 50 cc. of sulphuric acid (sp. gr. 1.84) will oxidize all of the organic carbon and liberate all carbon dioxid chemically or mechanically held in soils, provided the soil is ground to pass 60-mesh sieve and from 1 to 3 gm. of soil used for each 60 cc, of mixture. The Brown and Escombe titration method of determining carbon dioxid, and the modified Amos absorption tower for the same, are applicable to either wet or dry combustion forms of apparatus, and can be relied upon to give rapid and accurate results with considerable economy of time and space. Carbon may be accurately determined in 1 per cent hydrochloric acid extracts and 4 per cent ammonium hydroxid humus solutions without concentrating below 50 cc. by using the above chromic and sulphuric acid mixture. The apparatus described is applicable to the determination of carbon dioxid in any form, and a number of other gas determinations, depending on absorption in acid or alkalis, oxidation, or reduction processes. By using the apparatus shown, and following the method as outlined, one analyst can run six determinations at one time, and complete a set an hour when doing routine work."

An improvement in the electrical method of determining salt in soil, W. BEAM and G. A. FREAK (Cairo Sci. Jour., 8 (1914), No. 93, pp. 130-133, pl. 1).— In operating under field conditions with the electrical conductivity method it was found desirable to eliminate as far as possible the influence of calcium sulphate contained in the soil. This may be readily and satisfactorily done by employing, in place of water, diluted alcohol (40 per cent by volume) for the extraction of the salt, and by comparing with a table of resistance in the same solvent.

"Further, it is possible to extend the method to the determination of the proportion of calcium sulphate, since it is only necessary to make another extraction, with water, on a fresh sample, and from its conductivity and that of the salt known to be present, to determine the proportion of calcium sulphate by a simple calculation. An attached chart shows the curves of resistances of sodium chlorid in water, calcium sulphate in water, and sodium chlorid in alcohol of 40 per cent. The greater proportion of salt in most Nile soils is made up of sodium chlorid and sodium sulphate, but the resistances of these two are so nearly alike that for all practical purposes the one curve suffices.

"The method was tested on solutions of known composition, as follows: A water solution containing 0.03 per cent gypsum and 0.037 per cent sodium chlorid was found to have a resistance of 210 ohms as against a calculated resistance of 220 ohms. A water solution containing 0.015 per cent of gypsum and 0.018

a Jour. Chem. Soc. [London], 37 (1880), pp. 617-625.

^b Jour. Chem. Soc. [London], 89 (1906), pt. 1, pp. 595-597, fig. 1.

per cent of sodium chlorid was found to have a resistance of 410 ohms as against a calculated resistance of 420 ohms."

A modified Kjeldahl flask for determining soil nitrogen, H. A. Noyes (Jour. Amer. Chem. Soc., 36 (1914), No. 12, pp. 2541, 2542, fig. 1).—This modified flask is said to do away with the bumping and consequently makes a transfer unnecessary. The flask has the same proportions as the ordinary Kjeldahl bottles, but has a more pointed bottom.

Methods for the chemical, biological, and bacteriological examination of water, O. Emmerling (Praktikum der Chemischen, Biologischen und Bakteriologischen Wasseruntersuchung. Berlin: Borntraeger Bros., 1914, pp. VII+200, figs. 171).—This work deals with the analysis of drinking water and other waters. In the chapter on the examination of mineral water the determination of radio-activity is included. The biological portion considers the examination of sediments (living and dead matter), while the bacteriological section gives general and special methods for detecting Bacillus coli, B. anthracis, B. typhosus, and the cholera vibrio. The interpretation of results of water analyses is also included.

Hypothetical combinations in water analysis, R. B. Dole (Jour. Indus. and Engin. Chem., 6 (1914), No. 9. pp. 710-714).—This paper discusses the present confusing condition in regard to the reporting of results of water analysis. It shows the advantages of reporting the results in ionic form.

Methods of estimating carbohydrates.—II, The estimation of starch in plant material, W. A. Davis and A. J. Daish (Jour. Agr. Sci. [England], 6 (1914), No. 2, pp. 152-168, figs. 1).—Continuing previous work (E. S. R., 32, p. 112), the authors conclude that "the Sachsse method a of estimating starch is unreliable in the case of plant material; not only does the presence of pentosans falsify the results, as pentoses are formed during the hydrolysis, but actual destruction of dextrose occurs during the prolonged treatment with dilute acid. O'Sullivan's method gives low results, owing to the loss of dextrin which occurs during the purification of the solution after the conversion by diastase."

"To estimate starch, the dry material (free from sugars and, if necessary, previously extracted with water to remove gums, amylans, etc.) is gelatinized with 200 cc. of water in a beaker flash heated for one-half hour in a water bath at 100° C. The solution is cooled to 38°, 0.1 gm. taka-diastase added, together with 2 cc. of toluene, and the mixture left 24 hours in order that the conversion may take place; it is then heated in a boiling water bath to destroy the diastase and the clear solution above the residual leaf material is filtered through a fluted filter paper into a 500-cc. measuring flask; the leaf residue is thoroughly washed several times by decantation, the washings being passed through the filter paper until the volume of liquid in the flask amounts to about 475 cc. The necessary quantity of basic lead acetate is then added to precipitate the tannins, etc., present in the solution; the amount required varies considerably with different leaves, generally ranging from 5 to 25 cc. A large excess of lead should be avoided and tests should be made after each small-addition of lead acetate in order to ascertain when the precipitation is complete. When this is the case, the solution is made up to 500 cc. at 15° and filtered; 100 cc. of the filtrate is placed in a 110-cc. measuring flask, the slight excess of lead precipitated by adding solid sodium carbonate and the volume adjusted to 110 cc. at 15°. Fifty cc. of the filtrate from the lead carbonate is used for the reduction and another portion polarized in a 400-mm, tube.

The method of calculation is explained.

Sitzber. Naturf. Gesell. Leipzig, 5-7 (1877), pp. 30-37.

The chlorin number, a new constant for fat, A. Zlataroff (Ztschr. Untersuch. Nahr. u. Genussmit., 26 (1913), No. 7, pp. 348. 349).—The cumbersome procedure necessary for determining either the iodin or bromin numbers of fats led the author to study the value of chlorin as a fat constant. After studying a number of chlorin compounds and halogen transmitters, phenyliodid-chlorid, which can be easily and rapidly prepared, was chosen. The procedure used for determining the chlorin number was then as follows:

Weigh off 0.25 gm, of triolein (this was used in the test) in a Sendtner flask such as is used for determining the iodin number; mix with 60 cc. of carbon tetrachlorid, previously saturated at room temperature with phenyliodid chlorid prepared by Willgerodt's method, and allow the mixture to stand for four hours. In another Sendtner flask place 60 cc. of the phenyliodid-chlorid solution, and allow this also to stand for four hours. At the end of this time add 40 cc. of a titrated silver nitrate solution (1 cc.=0.0102 gm, silver) to each flask and shake. Then add a few drops of iron alum solution and determine the excess of silver nitrate with ammonium sulphocyanid solution (1 cc.=0.54 cc. silver-nitrate solution or 0.0515 gm, of silver). The difference between the two titrations represents the chlorin fixed by the fat.

For triolein the values fluctuated between 273 and 300.

The quantitative estimation of the salt-soluble proteins in wheat flour, G. A. Olson (Jour. Indus. and Engin. Chem., 6 (1914), No. 3, pp. 211-215).—Continuing previous work (E. S. R., 31, p. 208) and with a view to finding a correct method for the estimation of edestin and leucosin proteins in flour, it was found that a 1 per cent solution of sodium chlorid extracts gliadin to the extent of approximately 29 per cent of the total proteins present, while a 10 per cent solution extracts it to the extent of only 5 per cent.

A method is described whereby the edestin and leucosin nitrogen determination can be made in flour and its products, a correction being applied for the gliadin extracted.

"The amount of nitrogen bodies extracted with salt solutions and directly coagulated by heat varies with the concentration of the solvent. The 10 per cent concentration gives higher results than were found possible with a 1 per cent salt solution."

An investigation of the presence of furfurol in cider vinegar, Agnes A. Anderson (Jour. Indus. and Engin. Chem., 6 (1914), No. 3, pp. 214, 215).—Pure cider vinegar may contain furfurol as a natural constituent; therefore its presence can not be taken as indicating that either wood acetic acid or caramel has been added. Cider vinegars may give a test for caramel by the Ronnet method without containing furfurol or added caramel; hence the method is not reliable.

The analysis of maple products.—III, The range of variation of analytical values in genuine maple sirups, J. F. SNELL and J. M. Scott (Jour. Indus. and Engin. Chem., 6 (1914), No. 3, pp. 216-222).—Continuing the work previously noted (E. S. R., 31, p. 611), the author reports the results of examining 126 samples of genuine Canadian maple sirup. The range of conductivity value, in these sirups is determined for 20° and 25° C., and the range of the various analytical values in genuine maple sirups is compared with reference to these results and to those of Bryan (E. S. R., 24, p. 266), Jones (E. S. R., 17, p. 1038), and McGill (E. S. R., 26, p. 661).

"The values of narrowest range are the conductivity value, the alkalinity of the soluble ash, the weight of the total ash, and the Winton lead number. A scheme of rapid analysis is proposed, embracing determinations of the aforesaid values and of the Canadian lead number."

The reductase (fermentation reductase) test, R. Dons (Centbl. Bakt. [ctc.], 2. Abl., 40 (1914), No. 1-8, pp. 132-153; abs. in Berlin, Tievärztl, Wehnschr., 30 (1914), No. 22, p. 388).—The author concludes that the reductase test can not serve as a substitute for the counting (plating) of micro-organisms, decolorization of the dye the organisms grown at 38° C, were very active, and the results varied with pure cultures according to whether raw, pasteurized, or sterilized milks were tested. He believes that the micrococci and streptococci which form lactic acid probably decide the outcome of the reductase test. Bacteria of the coli aerogenes group reduced methylene blue as rapidly as true lactic acid bacteria, but more slowly in milk which had been pasteurized and sterilized. The test, however, will not decide how many bacteria are present. Bacteria which do not grow at 38°, or do so only sparingly, reduce methylene blue only when they are present in large numbers. An addition of human or horse feces to ordinary milk did not (even in large amounts) influence the reductase test when the milk had stood for two hours after adding the excrement.

Milk which had been heated for a long time at 100° or for a short time at 135° was capable of reducing methylene blue. Milk heated 10 minutes at 68 to 70° still produced the reductase test as in raw milk. The presence of a small amount of methylene blue in milk will check the development of bacteria, and the use of the reductase test in conjunction with the fermentation test was not tested by the author because it seemed to be of no value from a hygienic standpoint.

Manufacture and use of unfermented grape juice, G. C. Husmann (U. S. Dept. Agr., Farmers' Bul. 644 (1915), pp. 16. figs. 14).—"It is the purpose of this publication to state briefly the way in which unfermented grape juice is made and preserved, both for commercial and domestic use, as well as the fundamental processes and principles involved, and to offer practical suggestions." The subject is dealt with under the following headings: Composition of the grape; analyses of grape must; causes of fermentation; methods of preventing fermentation; flavor and quality of grape juice; home manufacture of grape juice; valuable appliances for home use; commercial methods of making must; and the use and food value of unfermented grape juice. A few thoroughly tested recipes prepared with unfermented grape juice are included.

Some abnormal factors of so-called farmers' cider vinegars, J. C. Diggs (Jour. Indus. and Engin. Chem., 6 (1914), No. 3, pp. 215, 216).—This gives the results of examining 18 samples of cider vinegar which were entered in an apple product exhibit of an apple show held in Indiana.

"The results of these analyses show the uncertainty of unscientific methods in the manufacture of vinegar. Pernicious practices exist among farmers who put vinegar on the market. Fraudulent vinegars are often sold as farmers' cider vinegars."

Hop investigations (Oregon Sta. Rpt. 1913-14, pp. 17, 18).—From a study made of the chemical changes of hops due to treatment with sulphur dioxid fumes the following conclusions are drawn:

"There is nothing to indicate that sulphuring in the bleaching process affects the bitter resins. The resin of the 'sulphured' hop contains no sulphur. The sulphur dioxid does not combine with the essential oil of the hop. The 'unsulphured' hop contains sulphur in the sulphate form, but no sulphur which is volatile by the ordinary steam distillation. Different samples of 'sulphured' hops contain different amounts of sulphur, both total and volatile with steam. There seems to be no definite proportion between the volatile sulphur and the total sulphur. The amount of sulphur present in the unsulphured Oregon hop is practically constant. The analytical methods which have been in use for the

estimation of the amount of 'sulphuring' are unreliable. Methods for determining quantitatively the different forms in which sulphur is found in the 'sulphured' hop have been worked out." See also work previously noted (E. S. R., 29, p. 534; 30, p. 115).

METEOROLOGY.

Report of the chief of the Weather Bureau, 1914 (U. S. Dept. Agr., Weather Bur. Rpt. 1914, pp. 256, pts. 4).—This contains an administrative report on work during the fiscal year ended June 30, 1914, and includes also tables giving a general summary of the weather conditions in the United States by months during the year 1913, an annual summary of climatological data at the Canadian stations for 1913, a list of observing stations and changes therein during 1913, sunshine in 1913, details of excessive precipitation in 1913, monthly and annual meteorological summaries for 1913, monthly and annual amounts of precipitation in 1913, and monthly and seasonal snowfall in 1913–14.

The administrative report notes, among other things, the inauguration during 1914 of a new special service for reporting the daily weather conditions over the principal range region of the West as affecting the live stock interests; the extension of snow surveys at high altitudes in some of the western States with reference to water supply, and of the use of a new form of snow scale or stake for this purpose; the extension of observations to secure better data for forecasting frosts in the citrus districts and in the orchards of the Northwest; and the improvement of the flood warning service.

Monthly Weather Review (Mo. Weather Rev., 42 (1914), Nos. 11, pp. 611-646, pls. 8; 12, pp. 647-702, pls. 43).—In addition to weather forecasts and river and flood observations for November and December, 1914, lists of additions to the Weather Bureau Library and of recent papers on meteorology and seismology, the weather of the month, a condensed climatological summary, and climatological tables and charts, the numbers contain these articles:

No. 11.—Remarks on the Nature of Cyclones and Anticyclones, by J. Hann; Halos and Precipitation at Wauseon. Ohio, by J. M. Kirk; Light Pillars, by Pernter and Exner; Halos, by C. S. Hastings; Systematic Explorations of the Upper Air with Estimates of Cost, by M. W. Harrington; Extracts from the Annual Report of the Smithsonian Astrophysical Observatory; The American Meteor Society, by C. P. Olivier; The Drexel Aerological Station; A Method for Classifying Winters, by A. Angot; Washington and Paris Winters, by C. Abbe, jr.; A Method for Classifying Summers, by A. Angot; Drought at New York City, by C. D. Reed; Notes on Ice and Mercury; and Meteorological Observations in Germany.

No. 12.—Solar Radiation Intensities at Washington, D. C., During October, November, and December, 1914, by H. H. Kimball; Photometric Measurements of Daylight Illumination on A Horizontal Surface at Mount Weather, Va., by H. H. Kimball; Heat from the Stars; E. Kron on the Extinction of Light in the Terrestrial Atmosphere in the Region of the Ultraviolet, by W. Schmidt; Present Status of Our Knowledge of the Causes of the Diurnal Changes in Temperature, Pressure, and Wind, by J. M. Pernter; Thunder, by W. Schmidt; The Place of Forestry Among Natural Sciences, by H. S. Graves; Why Some Winters are Warm and Others Cold in the Eastern United States, by W. J. Humphreys (see p. 811); Do Clouds Yield Snow Easier than Rain? by D. F. Manning; Foreign Distribution of the Monthly Weather Review during 1914 and 1915, by C. F. Marvin; Floods in New England Rivers, by A. J. Henry; and Seismology, by W. J. Humphreys. This number also contains a new section on selsmology containing seismological reports for October, November, and December.

Why some winters are warm and others cold in the eastern United States, W. J. Humphreys (Mo. Weather Rev., 42 (1914), No. 12, pp. 672-675).—Among the general facts and conclusions of this paper are the following:

"(1) Some winters in the eastern United States are unusually mild and others exceptionally cold. (2) During mild winters this part of the country temporarily has a marine climate, during cold ones a continental climate. (3) The type of winter climate, marine or continental, in this section is largely determined by the presence or absence of the Bermuda 'high.' (4) Persistence, during winter, of the Bermuda 'high' gives to the eastern United States a marine and, therefore, for it, an unusually mild climate. Continued absence of this 'high' during winter, allows a continental climate and, therefore, exceptionally low temperatures, to extend quite to the Atlantic coast. (5) The cause of the Bermuda 'high' seems to be a cold-water surface, a minimum surface temperature, along the belt of highs. (6) This low surface temperature in the region of the Bermudas may depend upon the temperature and strength of the Labrador current."

Predicting minimum temperatures for frost protection, J. W. SMITH (Ohio Nat., 15 (1915), No. 3. pp. 405-408, fig. 1).—This article explains a method by which the fruit grower can closely estimate the probable minimum temperature at critical periods. The method is based upon the average afternoon median temperature. Explicit rules to follow in the use of the method under different conditions are given.

Climate and meteorology of Australia, H. A. Hunt (Off. Yearbook Aust., 7 (1901–1913), pp. 59–85, figs. 9).—As in previous years (E. S. R., 30, p. 511) the more important meteorological and climatic features of Australia are described, and detailed data for temperature, pressure, precipitation, evaporation, and other phenomena for 1912 and preceding years are tabulated.

SOILS—FERTILIZERS.

Soil erosion in the South, R. O. E. Davis (U. S. Dept. Agr. Bul. 180 (1915), pp. 23, pls. 9, fig. 1).—This bulletin discusses the conditions affecting soil erosion as observed in a field study through the States of Virginia. Tennessee, Missouri, Mississippi, Alabama, Georgia, South Carolina, and North Carolina.

It is stated that owing to climatic, economic, and soil conditions, and the type of agriculture practiced, the South is especially susceptible to excessive erosion. "Methods of prevention should be practiced wherever hilly land is used for crops. Terracing is the best and most efficacious method, but should be supplemented by deep plowing and the incorporation of organic matter when permissible. The agricultural problem involves the adoption of proper crop rotation in connection with preventive methods best suited to soil conditions and crop production. The reclamation of eroded land is possible, but requires careful attention and patience. The use of such land for forestry is commonly advisable. Nature effects reclamation, but the process is slow and tedious."

See a previous note by the author (E. S. R., 31, p. 316).

Analysis of Florida muck soils, R. E. Rose (Ann. Rpt. State Chem. Fla., 1914, pp. 27-33).—The results of analyses of saw grass muck soils of the St. John's Valley, in St. Lucie County, are discussed with observations on the fertility of Everglade soils in general.

Geography of the soils of Georgia, F. A. MERRILL (Ga. State Normal School Bul., pp. 13, figs. 3).—This bulletin discusses the geographical distribution of the soil-forming rocks of the State of Georgia.

In the Appalachian highlands argillaceous and calcareous shales and limestones abound, the former producing red and brown loams and the latter a gray gravelly soil. In the Piedmont Plain the rock formation is crystalline, consisting mainly of granites, gneisses, and schists, from which are produced soils consisting mainly of gray sands of a gravelly nature, interspersed with many beds of red clay. In the Atlantic Coastal Plain the rocks are mainly cretaceous formations and later sediments, and consist of unconsolidated clays, sands, and marks.

Composition of the soils of the different glacial drift sheets, F. J. Alway (Minnesota Sta. Rpl. 1914, pp. 48, 49).—It is stated that physical and chemical analyses of samples of virgin soils from ten of the most southerly counties of Minnesota so far indicate that the phosphorus and postassium contents and the physical properties affecting the supply of moisture do not exhibit radical differences. As regards line content, the soils of the eastern counties are sharply distinguished from those of the western counties, as the former "carry a very small amount of line throughout the first 3 ft., while the latter, with certain exceptions, carry very large amounts in the third foot, considerable in the second foot, and some of them large amounts even in the first foot."

Soil survey of Orange County, New York, G. A. Crabb and T. M. Morrison (New York Cornell Sta. Bul. 351 (1914), pp. 747-800, fig. 1, map 1).—This survey, made in cooperation with the Bureau of Soils of this Department, deals with the soils of an area of 533,760 acres in southeastern New York, the topography of which ranges from nearly flat or rolling to mountainous. The entire county has been glaciated. The drainage is through the Hudson and Delaware Rivers.

The soils of the county are divided with reference to manner of formation into glacial residual, reworked glacial, recent alluvial, cumulose, and cumulo-alluvial soils. Forty types are mapped, of which the Dutchess silt loam and stony loam are the most extensive and most used for general farming and dairying. Muck is said to be the most valuable land in the county. Many of the soils, especially the muck and other bottom soils, need drainage.

The adaptation of soils to crops is recognized to some extent, but little effort is made to develop systematic crop rotations.

Soil analysis (Oregon Sta. Rpt. 1913-14, p. 19).—Analyses of samples of different types of soil occurring in the Hood River Valley revealed a marked nitrogen deficiency in many cases and occasional deficiencies in potash and lime.

The distribution of swamp land in the Kingdom of Bavaria (Übersicht über die Verteilung der Moore im Königreich Bayern. Munich: C. Gerber, 1913, pp. 11, pl. 1).—Data and a map are given showing that the total swamp land surface, including upland and lowland swamps, amounts to about 510,329 acres, of which about 95,687 acres are under cultivation.

Studies of an acid soil in Assam, A. A. Meggitt (Mem. Dept. Agr. India, Chem. Ser., 3 (1914), No. 9, pp. 235-269, pls. 7; abs. in Jour. Chem. Soc. [London], 106 (1914), No. 626, I, p. 1212).—In field experiments with oats on an acid alluvial light loam soil deficient in calcium carbonate and phosphoric acid, on which crops had repeatedly failed to survive the seedling stage, it was found that the application of lime made it possible to grow crops on the soil and that the lime was particularly effective if used in sufficient amounts to make the surface soil neutral or slightly alkaline.

Since applications of sodium, potassium, and magnesium carbonates also had more or less the same favorable influence on crop growth as liming, the author suggests that the beneficial effect may be attributable in part at least to neutralizing of soil acidity or the supplying of lacking basic constituents in the soil.

Since laboratory examinations "had already disclosed positively the presence of an acid organic compound, definitely toxic to jowar [Andropogon sorghum]

seedling plants in extremely dilute culture solution (30 parts per million), the toxicity of which was partly or wholly negatived by the addition of a complete nutrient solution containing nitric nitrogen, or by the addition of lime to neutrality," it was thought to be reasonably clear that the soil's infertility was due in no small part to the presence of toxic organic compounds which accumulate in acid soils deficient in basic constituents. This conclusion was further confirmed by the fact that the application of superphosphate was followed by beneficial effects on crop growth similar to those observed in the case of liming, and that the toxicity to sorghum seedlings observed in water cultures with extracts of the soil was diminished by the addition of phosphate, although it is recognized that the results with the superphosphate may have been due in part to the fact that it supplied a deticiency of phosphoric acid in the soil.

The colloid chemistry of humus, S. ODÉN (Kolloid Ztschr., 14 (1914), No. 3, pp. 123-130; abs. in Ztschr. Angew. Chem., 27 (1914), No. 88-89, Referatenteil, pp. 613, 614).—Studies of the humus of sphagnum peat in which the principles of colloid chemistry were used in an attempt to isolate the individual constituents of humus are reported.

Three substances, two of which were colloidal and one noncolloidal, were obtained from the water extract of the peat. Also substances exhibiting distinctly colloidal properties were obtained from the ammonia extract. Tests of some of these as regards electrical conductivity indicated the presence of active acids which are thought to be the main constituents of humus acids. Further tests of the electrical conductivity of a solution of pure humus in very dilute ammonia verified these results. The author considers this to be conclusive evidence as to the existence of humus acids.

A note referring to similar work by Ehrenberg and Bahr is appended.

Soil colloids and the soil solution, F. K. Cameron (Jour. Phys. Chem., 19 (1915), No. 1, pp. 1-13).—The author comments on the loose use of the term colloid as applied to soil chemistry, reviews the arguments of others advanced to demonstrate the existence of colloids in soils, and attacks the popular theories regarding the supposed relations between soil phenomena and soil colloids on the grounds that they have no definite experimental basis.

He points out that many of the soil phenomena attributed to soil colloids can be accounted for by the mere fact that the soil particles present a large surface for absorbent action. He is of the opinion, however, that soil chemistry can be considered a branch of colloid chemistry provided a colloid is defined as a phase sufficiently divided where surface phenomena are predominant,

"The relation of the gas-liquid surface tension to the solid-liquid surface tension is a most important problem requiring investigation for a clear purview of the functions of soil colloids. It is a necessary consequence of the colloid constitution of the soil that very small changes in the concentration of the soil solution correspond to relatively large changes in the composition of the solid phases respecting those constituents derived from the minerals of the soil."

Soil water in relation to plant growth, W. J. Colebatch (Jour. Dept. Agr. So. Aust., 18 (1914), No. 4, pp. 363-374).—The author discusses the functions of soil moisture, with particular reference to plant growth in excessively wet soils.

Experiments on the effect of varying water and food supplies on the water requirements of oats showed that plants do better in dry seasons when the food supply is plentiful and that in dry years a portion of the manure is lost to the crop. Further experiments with oats on the influence of water supply on the effectiveness of phosphates bore out the conclusion that the water supply exerts an important influence on the effectiveness of fertilizers.

The author further discusses gravitational water and soil drainage, reviewing the work of others bearing on the subject and pointing out particularly the importance of soil drainage in regulating the soil moisture content, soil aeration, soil temperature, and the physical condition of the soil.

Effects of variations in moisture content on certain properties of a soil and on the growth of wheat, F. S. Harris (New York Cornell Sta. Bul. 352 (1914), pp. 805-868, fig. 1).—The work of others relating to the subject is briefly reviewed and greenhouse and laboratory experiments with wheat plants grown in pots containing clay loam soil subjected to different moisture and fertilizer treatments, and studies of certain properties of cropped and uncropped soils standing for long periods under these conditions are reported.

It was found that the cropped soil was more compact than the uncropped and the volume of the soil decreased as the moisture content increased. tilized soils with crops were more compact than unfertilized soils. tion was greater in cropped than in uncropped soils and was greater with a medium degree of soil moisture than with a very large or very small degree, the least flocculation occurring in the very wet soil. Flocculation was increased by fertilizers, especially those containing little sodium nitrate. uitrate content was always greater in uncropped than in cropped soil and in soils to which nitrate fertilizers had been added, and was greater with 30 per cent moisture than in a drier or a wetter soil. Soil constantly saturated with moisture contained practically no nitrates. The nitrite content of the soils was always low but was higher in the uncropped soil than in the cropped, and was higher where high nitrogen fertilizers had been added. The ammonia content, while never great, was always higher in cropped than in uncropped soils, was highest where a high nitrogen fertilizer was used, and was not much affected by the soil moisture. The ratio of soluble salts to nitrates was always higher in cropped than in uncropped soll.

While not definitely determined, the number of bacteria in the soil was usually greater with 15 than with 30 per cent moisture and was slightly greater in unfertilized than in fertilized soil. The easily soluble phosphoric acid was always higher in the uncropped than in the cropped soil, higher in the fertilized than in the unfertilized soil, and varied irregularily with the soil moisture.

Wheat matured sixteen days earlier with 20 per cent molsture than with either 11 or 45 per cent and a well-balanced fertilizer caused an earlier maturity than one with high nitrogen or no fertilizer. Tillering was promoted by high moisture and by fertilizers. Plants were able to stand excessive moisture better when young than when older and mildew attacks were severest on plants growing with high moisture and a high nitrogen fertilizer.

"The number of nodes per culm was least with a medium, and most with the very high, soil moisture. The length of culms and of heads increased with the moisture up to $37\frac{1}{2}$ per cent, after which both decreased. The heads were proportionately longer in the dry than in the wet soil. The quantity of moisture during the early growth, more than at any other time, determined the head as well as the culm length. Fertilizers increased the number of nodes per culm, as well as the length of culm and of head." The number of kernels of wheat per pot and the quantity of straw increased with the fertilizers, and with the soil moisture up to $37\frac{1}{2}$ per cent, above which it decreased. The number of kernels per head was greatest on the soil with a medium amount of moisture but the weight of 100 kernels was greatest on the very dry soil and least on the very wet. There was proportionately more grain than straw when the soil moisture was low during the early stages. Proportionately more of the dry matter in wheat had been produced by the boot stage in the dry soll than

in the wet, after which the weight of roots which could be washed out decreased to maturity. The greatest transpiration was in the plants producing the most dry matter. In relation to dry matter produced, water was transpired most economically with a medium degree of soil moisture but was used most economically in the production of grain when the soil was kept comparatively dry up to the boot stage and then kept wet until maturity. The total dry matter in the plant as a whole, however, was produced most economically when the soil was kept wet until the five-leaf stage and drier from then until maturity.

The percentage of nitrogen in both grain and straw was highest on the driest soil and gradually decreased as the moisture increased up to 37½ per cent, but as the soil approached saturation the percentage of nitrogen in the grain slightly increased. The condition that gave the highest percentage of nitrogen both in the grain and straw was where the moisture was low up to the boot stage and high from that stage to maturity. The lowest nitrogen was found where the moisture was high during all periods. The high nitrogen fertilizer always increased the nitrogen content of the crop. While the percentage of nitrogen was not so great in the crop produced with complete fertilizer as with no fertilizer, the total weight of nitrogen was much greater, due to the larger crop. The decrease in the percentage of nitrogen from the boot stage to maturity was greater in the crops on the wet soil than in those on the dry soil.

The percentage of crude ash, calcium, magnesium, potassium, and phosphoric acid was lower in wheat straw grown with high moisture than in that grown with low moisture.

"These experiments bring out clearly the facts that the moisture relations of plants are greatly affected by the fertility of the soil, and that the effect of a fertilizer is dependent on the amount of soil moisture. They emphasize also the fact that fertilizer experiments, in order to be of value, must be made under widely varying moisture conditions, and that experiments with the use of moisture by plants, in order to be conclusive, must include a number of fertility conditions."

A list of references to related literature is appended.

The evaporation of water from soil, B. A. KEEN (Jour. Agr. Sci. [England], 6 (1914), No. 4, pp. 456-475, figs. 8).—Studies on water evaporation from the fine sand and clay soil fractions, from china clay, and from soils, with particular reference to the factors governing evaporation in soils, are reported and the apparatus and methods used described.

It was found that the evaporation of water from the soil fractions, from china clay, and from ignited soil is a phenomenon readily explainable by the known laws of evaporation and diffusion. In the soils, on the other hand, the evaporation was more complex, indicating the presence of a factor which causes a more intimate relation between the soil and the soil water. The removal of the soluble humus from the soil by means of 2 per cent caustic soda did not appreciably affect the evaporation, and ignition of the fine sand and silt made no appreciable difference in the evaporation from these fractions, thus largely eliminating any possible effect of the insoluble organic matter. Destruction of the colloidal properties of the clay fraction completely altered the evaporation curve, which became identical with that given by sand or silt.

It is concluded, therefore, "that the colloidal properties of the clay fraction are in part, if not mainly, responsible for the characteristic shape of the evaporation curve from soil."

In a mathematical study of the rate of evaporation from soil (the first differential of the experimental curves) two factors were distinguished which oper-

ated over practically the whole range of water content dealt with in the experiments, one expressing the effect of the gradually diminishing water surface on evaporation and the other giving an empirical measure of the influence of the vapor pressure of the moist soil. The following equation for rate of evaporation from soil was developed:

$$A\frac{dw}{dt} = \sqrt[3]{\left(\frac{ws}{100} + 1\right)} [2.303 \log_{10}(w+K) - \log_e K], \text{ where } \frac{dw}{dt} = \text{rate of evaporation.}$$

w=percentage of water present by weight.

s=specific gravity of the soil.

A and K = constants.

Partial sterilization of soil by volatile and nonvolatile antiseptics, W. Buddin (Jour. Agr. Sci. [England], 6 (1914). No. 4, pp. 417-451, figs. 4).—Supplementing previous experiments by Russell and Hutchinson and others (E. S. R., 31, p. 27) further tests were made by the Russell and Hutchinson method on two soils, one high and the other low in nitrates, to compare a wider range of substances including benzene, toluene, cyclohexane, pentane, hexane, heptane, chloroform, ether, acetone, formaldehyde, alcohols, phenol, cresol, hydroquinone, pyridin, calcium sulphid, sulphur, sulphur dioxid, sodium fluorid, and sodium chlorid. The object of these tests was to determine whether the phenomena observed in the earlier experiments in the case of toluene and a few other substances are generally true of antiseptics, including (1) those which are completely volatile and disappear entirely from the soil when their work is done and (2) those which remain in the soil for a considerable time or else leave decomposition products and so exert a prolonged action upon the bacterial flora of the soil and upon the plant.

It was found that the characteristics of true partial sterilization are common to a large number of antiseptics, and consist in an initial decrease in bacterial numbers followed by a large sustained increase, the killing of protozoa and nitrifying organisms, an initial increase in ammonia followed by a considerable increase in the rate of ammonia production, and no change in the results obtained following an increase in the dose in any particular chemical when once true partial sterilization has taken place. True partial sterilization was obtained only with the easily volatile or removable antiseptics, the dose of the more important of these necessary for this purpose being as follows: Benzene, below 0.15 per cent by weight of dry soil; toluene, 0.09; cyclohexane, 0.17; pentane, 0.7; hexane, 0.17; heptane, 0.1; chloroform, below 0.24; ether, below 1.5; and acetone, 5.8.

"Substances not completely removable from the soil have some lasting influence on the flora. With the weaker doses two or three special species of bacteria characteristic of the chemical used multiply temporarily to an enormous extent, but the organisms do not produce ammonia, consequently there is no gain in ammonia and nitrate as the result of their action. The higher doses permanently suppress all microbiological action in the soil.

"It appears to be a general rule that a simple flora can attain extraordinarily high numbers, while a complex flora, such as prevails after normal partial sterilization, does not attain to higher numbers than the comparatively low level of about five times those in the untreated.

"It is possible to trace a certain relationship between the action of all the substances used. The intensity of the effects shades off gradually from that of the powerful nonvolatile antiseptics through cresol and formaldehyde to the more and less potent volatile antiseptics respectively, till finally the action of merely spreading out the soil in a thin layer is reached [see abstract below]."

The author concludes that "volatile antiseptics are undoubtedly effective in increasing the productive capacity of a soil under laboratory and pot culture house conditions, but are unsuitable for application on the larger scale. An efficient solid substance would be very convenient in use and probably much cheaper than methods of partial sterilization by heat." The experiments thus far made "have not revealed any suitable new nonvolatile substance. They have, however, emphasized the value and explained the action of phenol and cresol and have emphasized, although they have not explained, the action of formaldehyde" in causing an initial increase in ammonia but an irregular inhibition of nitrification.

Note on the increased nitrate content of a soil subjected to temporary drying in the laboratory, W. Buddin (John. Agr. Sci. [England], 6 (1914), No. 4, pp. 452-455).—In the course of the experiments noted above it was found that the untreated soils, spread out at the same time the treated soils were spread to evaporate the antisepties, contained after a period of incubation considerably more nitrate than similar soils which had been kept permanently moist. The soils originally contained only a little more ammonia and nitrate than the moist soil and when dried contained less rather than more bacteria. This increased amount of nitrate "appears to be due not to absorption from the atmosphere but to the formation of more nitrate from the residues in the soil in spite of the fact that the numbers of bacteria are not increased."

These results are considered important in that they show the necessity of spreading the untreated soil side by side with the treated to avoid error in all work with volatile antiseptics.

Ammonification studies with soil fungi, H. C. McLean and G. W. Wilson (New Jersey Stas. Bul. 270 (1914), pp. 3-39, fig. 1).—Ammonification studies using dried blood and cotton-seed meal with an acid gravelly loam and a neutral red shale as media are reported, the main purpose being to determine the ammonifying efficiency of the fungi present in the soil. Preliminary experiments on the effect of acid phosphate and acid phosphate and lime on ammonia accumulation in soils and on the effect of acid phosphate on the ammonification of dried blood by bacteria indicated that fungi rather than bacteria were responsible for the large accumulations of ammonia in soils containing acid phosphate and organic nitrogen in the form of dried blood.

In a series of ammonification experiments with pure cultures of fungi, it was found that of the fungi studied, including members of the Aspergillaceæ. Mucoraceæ, Dematiaceæ, and Moniliaceæ, all had the power of ammonifying both cotton-seed meal and dried blood. Fungi belonging to the Moniliaceæ were the most active ammonifiers.

"The individual members of this group showing the highest ammonifying efficiency were *Trichoderma koeningi* strain v. 2 and *T. koeningi* strain v. 3. The latter fungus gave the maximum ammonia accumulation in the soil of any fungus studied, from both cotton-seed meal and dried blood. The highest ammonia accumulation was from the dried blood. The Aspergillaceæ contained the species showing the least ammonifying power. . . .

"Where dried blood was used as a source of nitrogen, acid phosphate was found to increase the ammonia accumulation in the soils with 18 out of the 26 pure cultures of fungi studied. On the other hand, where cotton-seed meal was added as a source of nitrogen, ammonia accumulation was increased only in the case of 8 out of the 25 cultures used in the test. . . .

"All of the fungi with the exception of four, viz, Zygorrhynchus vuilleminii, Rhizopus nigricans, Monilia sitophila, and Mueor hiemalis, were able to ammonify dried blood more readily than cotton-seed meal. The results of these experiments make it appear that the ammonification of the soil organic matter, by fungi, depends not only upon the chemical and physical composition of the

soil, but also upon the quality of the organic matter present, as well as on the presence of soluble phosphates."

A contribution on the nitrogen problem, H. Scheerlinek (Handel Vlaamsch Natuur en Geneesk, Cong., 17 (1913), pp. 192, 193).—A study carried out with a diplococcus, abundant in certain soils and water therefrom, is held to show that during the process of fermentation organic nitrogen takes part in the formation of ammonia.

Soil bacteriological investigations (*Oregon Sta. Rpt. 1913-14, pp. 18, 19*).— It has been found that lime seems to increase the ammonifying and nitrifying efficiency of the soils of western Oregon in a marked manner. The effect is less noticeable on eastern Oregon soils.

[Soil inoculation] (Oregon Sta. Rpt. 1913-14, pp. 19, 20).—Direct benefit was derived in 69 per cent of the cases in which cultures of bacteria, sent out by the station in 1912 for the inoculation of legumes, were used.

The results of some experiments with farmyard manure, R. A. Berry (West of Scot. Agr. Col. Bul. 65 (1914), pp. 177-251, figs. 4).—Experiments extending over a number of years on the storage of manure under cover and in the field, on the storage of different kinds of fresh manure in heaps in the field, on the treatment of manure during storage, and on times and methods of applications of manure, and comparing fresh v, rotted manure and large v, small applications of manure are reported.

When stored for four months in well trodden heaps the indoor manure lost 17.5 per cent in weight and the outdoor manure 20.6 per cent, with an average annual rainfall of 39.32 in. The indoor manure lost 20.4 per cent of its nitrogen and practically none of its phosphoric acid and potash, while the outdoor lost 28.4 per cent of its nitrogen, 21.1 of its phosphoric acid, and 28.3 of its potash. The rotted manures were in each case poorer in total and available nitrogen than the fresh, the losses in this respect being greater in the outdoor than in the indoor manure. The greatest loss was in ammoniacal nitrogen, amounting to from 70 to 80 per cent of that of the fresh manure, 18 per cent of the total nitrogen of which was in ammoniacal form. There was a slight increase of amid and of insoluble nitrogen in the rotted manure. There was no loss of phosphoric acid and potash where there was no drainage. The average increase of crop (potatoes and turnips) in favor of manure stored under cover was 7 per cent.

The average loss in weight of horse manure with peat moss and with straw litter, cow manure, steer manure, and pig manure stored in the open for four months (December to March) was 22.3 per cent. With the moss litter the loss from horse manure was much less than with straw (12.6 and 14.9 per cent, respectively). The two fresh manures richest in nitrogen, namely, those from fattening steers and from horses (with peat moss litter), were left poorer in this constituent after rotting, while the fresh manures relatively poor in nitrogen, namely, those from cows, pigs, and horses (with straw litter) in the order named were left slightly richer in total nitrogen after rotting. In the rotted manure on the average 4 per cent of the total nitrogen was ammoniacal and 82 per cent insoluble as compared with 15 and 72 per cent, respectively, in the fresh manure. Forty-four per cent of the phosphoric acid and 71 per cent of the potash in the rotted manure was soluble in water as compared with 53 and 76 per cent, respectively, in the fresh. "The average loss of manurial constituents in the five manures during rotting was: Total nitrogen, 29.6 per cent; total phosphoric acid, 12.2 per cent; total potash, 33.5 per cent." Rotting in every case lowered the fertilizing value of the manure as measured by its power of supplying available fertilizing constituents. This was borne out by experiments with potatoes and turnips.

"Of the substances added to the manure to fix ammonia, gypsum and sodium acid sulphate were the most efficient, but superphosphate of lime, kainit, and carbonate of lime increased the loss of nitrogen. Of the antiseptics added to check fermentation, chloroform acted best, followed by bleaching powder and formalin. The reduction in the loss of nitrogen, where such occurred, was, however, not sufficient in any case to repay the cost of the substance used. The most effective method of preserving the manure from losses of nitrogen was to trample the manure and to cover it with a 3-in, layer of soil."

Fresh and rotted manure was applied broadcast and in drills in autumn and spring on two rotations, (1) potatoes, wheat, grass, and oats, and (2) turnips, barley, grass, and oats, with the result that fresh manure applied in drills in the spring gave uniformly the best results both with the root crops and for the whole rotation. "About 9 per cent of the increase for root crops of the drilled manures was due to the method of applying the manure in drills over that of broadcasting. In the case of the autumn application of manure, when the manure was applied to turnips, there was a 5 per cent increase in favor of plowing in the manure at once compared with leaving the manure on the surface some time before plowing it in. When the manure was applied to potatoes there was not much to choose between the two practices." In the potato rotation about 50 per cent of the total increase due to the manure was accounted for in the first crop (potatoes) and the manurial residue was not exhausted at the end of the rotation. In the case of the turnip rotation 65 per cent of the total increase was accounted for in the first crop (turnips) and the manurial residue was practically exhausted by the second crop. "Farmyard manure yields, when applied in drills in spring to potatoes, about 60 per cent, and to turnips about 80 per cent, of its total manurial value for the rotation, compared to a yield of about 40 per cent with potatoes and about 50 per cent with turnips when the manure is applied broadcast in the autumn. Small dressings of manure, of about 10 tons, produce proportionately a better return with the first crop than large dressings of about 20 tons, but the latter leaves proportionately a larger residue than the former."

From comparative tests of fresh v. rotted manure applied at rates of 20 tons per acre in drills in the spring it was concluded that the relative efficiency of the manures depends largely upon the amount of available nitrogen which they are capable of yielding to the erop, although, as a rule, short rotted manure produces better results on light soils than long fresh manure. Large applications (20 tons per acre) of manure to potatoes left a manurial residue in the soil which produced a notable increase on the fourth crop following the application of the manure. With turnips the residual effect was hardly visible after the second crop. Small applications (10 tons per acre) produced no effect after the second crop. The addition of superphosphate, potassium sulphate, and ammonium sulphate to the manure did not affect this result, showing that the artificial fertilizers were exhausted by the crop to which they were applied.

The article gives numerous analyses of different kinds of manure, especially a series of analyses of cow manure from 12 typical dairy farms which showed total nitrogen, 0.237 to 0.462, average 0.346 per cent; ammoniacal nitrogen, 0.024 to 0.129, average 0.064 per cent; phosphoric acid, 0.170 to 0.428, average 0.266 per cent; and potash, 0.263 to 0.497, average 0.381 per cent.

Results of two years' work on London Soil Experiment Field, G. ROBERTS (Kentucky Sta. [Circ.], pp. 3).—Comparative tests of different fertilizers on a rotation of corn, wheat, and cowpeas on a fine sandy loam, especially deficient in nitrogen, phosphoric acid, and calcium carbonate, but containing a fair proportion of potash, showed that the most profitable method of improving such a

soil is to use phosphate, limestone, and manure in connection with a crop rotation similar to that followed in the experiments reported.

The economic importance of peat moors and water powers, with special reference to the air-nitrogen question, A. Benetsch (Die volkswirtschaftliche Bedeutung der Torfmoore und Wasserkräfte unter besonderer Berücksichtigung der Luftstickstoff-Frage. Berlin: F. Siemenroth, 1914, pp. V+229, pls. 7, figs. 17; abs. in Zlschr. Moorkultur u. Torfrerwert., 12 (1914), No. 5-6, p. 214).—This book is divided into a general introduction and three parts, dealing, among other things, with (1) the economic importance of peat and peat moors from both industrial and agricultural viewpoints, containing a discussion of the manufacture of illuminating gas and ammonia from peat by the Mond-Frank-Caro processes as well as the use of moor soils for agricultural purposes; (2) the development and use of water power, especially for the production of electric power; and (3) the electrical production of nitrogen compounds from the free nitrogen of the air, dealing also with the question of the production of nitrogenous and other fertilizers and discussing particularly the calcium cyanamid and nitrate industry as developed in different countries.

The author holds that the nitrogen question has been satisfactorily solved by the electrical fixation of atmospheric nitrogen.

A bibliography of 212 references to the literature of the subject as well as a list of German patents relating to the electrical fixation of nitrogen are given.

The utilization of peat in Italy, U. Rossi (Bol. Quind. Soc. Agr. Ital., 19 (1914), No. 10, pp. 356–361; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 8, pp. 1005, 1006; Milt. Ver. Förd. Moorkuttur Deut. Reiche, 32 (1914), No. 20, pp. 375, 376).—It is stated that there are a large number of workable peat beds in Italy, and that some attempt has been made at different times with little commercial success to utilize the peat for fuel and other purposes and to use the peat land for agriculture.

The most important industrial development with reference to the utilization of peat is, however, the establishment of plants at Orentano and Codigoro for the manufacture of illuminating gas and ammonia by the Mond process. It is stated that these plants are able to manufacture ammonia at somewhat less than half the market price of this product.

German and other sources of potash supply, C. H. MacDowell (Bul. Amer. Inst. Mining Engin., No. 98 (1915), pp. 103-114; Chem. Engin., 21 (1915), No. 2, pp. 45-50).—The German deposits and mining methods are described, with data on cost, commercial conditions, and consumption. Other possible sources are also briefly discussed.

Among the latter are the deposits near Kalusz in Galicia, Austria, and the recently discovered deposits in Spain, which seem to be of commercial importance; deposits of nitrate of potash in Peru; the potash salts which may be obtained from sugar-beet waste, from wool scouring, and as a by-product in the manufacture of cement; the potash obtainable from kelp, alunite, feldspar, leucite, and from brines obtained from alkali lakes and ponds and from borings in Texas. As far as the United States is concerned, it is stated that "up to now Searles Lake is the only nearby producer on the map."

Further exploration and investigation of methods of utilizing the sources of potash named is urged.

Investigation of sources of potash in Texas, W. B. Phillips (Bul. Amer. Inst. Mining Engin., No. 98 (1915), pp. 115-127, figs. 3).—This article deals particularly with the potash brines obtained at Spur, Tex. (E. S. R., 28, p. 522), and with the occurrences of small amounts of potassium and sodium

nitrate in sandstones and other rocks and of small amounts of nitrates derived from bat guano in caves.

The conclusion is that the only hopeful outlook for the existence of workable beds of potash salts in Texas is in the brines as found at Spur and in the almost wholly unknown region southeast of and bordering New Mexico.

Potash from kelp, F. K. Cameron (U. S. Dept. Agr. Rpt. 100 (1915), pp. 122, pls. 40, figs. 2, maps 54).—This consists of a series of reports, accompanied by detailed maps of the kelp groves of the Pacific coast and islands of the United States and Lower California, on the following subjects: Pacific Kelp Beds as a Source of Potassium Salts, by F. K. Cameron; The Kelp Beds from Lower California to Puget Sound, by W. C. Crandall; The Kelp Beds of Puget Sound, by G. B. Rigg; The Kelp Beds of Southeast Alaska, by T. C. Frye; and The Kelp Beds of Western Alaska, by G. B. Rigg. These reports and maps are the result of careful surveys of all of the commercially available kelp beds from Cedros Island to Cape Flattery, about half the beds available in southeast Alaska, and the major part of the beds on the southern slopes of the Alaska Peninsula.

On the basis of a large number of analyses which show that the Pacific coast kelps, in a dry state, contain about 16 per cent of potash, corresponding to about 25 per cent of potassium chlorid, it is estimated that the 390 square miles of kelp beds already mapped on the Pacific coast are capable of producing annually 59,300,000 tons of fresh kelp, equivalent to 2.266,000 tons of potassium chlorid.

"What it would cost to obtain the pure potassium chlorid from kelp can not be stated, as sufficient experience is not yet accumulated to justify exact estimates. It should be easier to extract the potassium chlorid from kelp than from the Stassfurt salts. But the cost of harvesting the kelp as well as the subsequent manipulation is, at the present time, speculative. It is easy to show by 'paper calculations' enormous profits in obtaining pure potassium chlorid, iodin, and possibly other products from the kelp. Since, however, the dried kelp will average more than 25 per cent potassium chlorid, since the organic matter decomposes very readily, and there is present nitrogenous matter equivalent to about 2 per cent nitrogen and some phosphate, it seems probable that kelp in the dried state, either alone or in mixture with other materials, such as fish scrap and standard phosphate carriers, is the form in which it is most likely to find at first a market as a fertilizer.

"It is also impracticable to give any close estimate of the value of the possible kelp harvest. Assuming that all the potassium chlorid were extracted and marketed as such, the value at present prices would be approximately \$90,000,000, whereas if the crop were all reduced to dried kelp and sold at current figures for both potash and nitrogen content, the value would be in excess of \$150,000,000."

The general conclusion from the investigations already made is "that the commercial production of potash salts from American sources and in quantities sufficient to meet the growing needs of the Nation is quite practicable."

Radium as a fertilizer, C. G. Hopkins and W. H. Sachs (Illinois Sta. But. 177 (1915), pp. 389-401).—Experiments by others on this subject are reviewed, and field experiments with corn and soy beans in which the radium fertilizer was used at rates furnishing 0.01, 0.1, and 1 mg. per acre are reported.

The soy beans followed the corn on the same land without additional application of the radium fertilizer. Of six trustworthy average results with corn, three were for and three against radium. Of eighteen averages with soy beans, nine were for and nine against radium. In all cases the average variation

from the check was so slight and so evenly distributed for and against "as to lead only to the conclusion that radium applied at a cost of \$1, \$10, or \$100 per acre produced no effect upon the crop yields either the first or second season."

Attention is called to the fact that even if the radium fertilizer were to increase the crop yields "the effect would be that of a stimulant and the increase would be secured at the expense of the soil. Thus the soil would not be enriched in fertility, but actually impoverished by such treatment."

Fertilizer inspection (Maine Sta. Off. Insp. 62 (1914), pp. 105-140).—Analyses of samples of fertilizers collected under the direction of the Commissioner of Agriculture of Maine during 1914 are reported with a summary of the requirements of the state fertilizer law. Notes are also given on the valuation of fertilizers, the question of the potash content of fertilizers for 1915 in view of the present shortage of potash, the use of farm manure, and certain special results of the fertilizer inspection, including a statement by A. M. G. Soule.

AGRICULTURAL BOTANY.

Plant breeding, L. H. Bailey and A. W. Gilbert (New York: The Macmillan Co., 1915, rev. ed., pp. XVIII+474, figs. 113).—This is a revision of the work by Bailey, the fourth edition of which has been noted (E. S. R., 17, p. 1144). The work of revision has been largely done by the junior author and considerable new material has been added, bringing the subject up to date. Appendixes are given defining the terms used, with a bibliography of important contributions to plant breeding that appeared between 1905 and 1912, and laboratory exercises to be used in conjunction with teaching plant breeding.

Enothera grandiflora of the herbarium of Lamarck, H. de Vries (*Rev. Gén. Bot.*, 25 bis (1914), pp. 151-166, fig. 1).—The author concludes an account and discussion of his comparative study of preserved and of natural specimens made in 1895 and repeated in 1913, with the statement that since the time of Lamarck this species has been growing on the dunes near Liverpool in the same form as at the present, and that the original specimen described by Lamarck as **E**. grandiflora (the name having been changed by Seringe about 1828) agrees with the form now generally known as **E**. lamarckiana.

Experimental variations in Tricholoma nudum, L. Matruchot (Rev. Gén. Bot., 25 bis (1914), pp. 503-509, pl. 1).—It is stated that T. nudum, cultivated in darkness with normal humidity at 11° C. (51.8° F.), grows as vigorously as under natural conditions, but that it loses progressively certain of its characters, such as the violet pigment characteristic of the species and the gill sinus characteristic of the genus. These changes were noted in the specimens without exception, while the odor and other characters were not sensibly altered.

The presence of Orobanche minor on Pelargonium zonale, H. Scheerlingk (Handel, Vlaamsch Natuur en Geneesk, Cong., 17 (1913), pp. 194, 195).—Having found O. minor on P. zonale (it having strayed, supposedly, from clover growing near) to present certain anomalies as regards color and structure, the author grew this parasite on Geranium robertianum and obtained somewhat similar peculiarities.

Parasitic specialization, F. HESKE (Ztschr. Forst u. Jagduc. 46 (1914), No. 5, pp. 281-289).—This is mainly a theoretical discussion of some recent conclusions by several authors regarding the chemical relations between the hosts and the fungi, with their collaborating enzyms.

Chondriosomes in fungi, F. A. Janssens (Handel, Vlaamsch Natuur en Geneesk, Cong., 17 (1913), pp. 141-148, fig. 1).—Giving some results of obser-

vations made on the forms, arrangements, distribution, etc., of chondriosome elements alleged to exist in yeasts and in fungi studied in early stages of development, the author states that choudriosomes are abundant in fungi and are characterized by much the same appearance and peculiarities as in animals and higher plants.

Morphology of the barley grain with reference to its enzym-secreting areas, A. MANN and H. V. HARLAN (U. S. Dept. Agr. Bul. 183 (1915), pp. 32, pls. 8, figs. 7).—A special study has been made of the barley grain with a view to improving its quality. The authors give a report on the morphology of the grain, having investigated it both at rest and in germination.

It is claimed that the integuments of the ripe barley, with the exception of the investing membrane of the nucellus, are only protective. The membrane surrounding the nucellus develops into a semipermeable membrane, which has remarkable selective powers. In the development of the barley grain the endosperm is said to develop earlier and more rapidly than the embryo. At maturity the starch is less dense about the periphery of the endosperm than in the center, and the epithelial layer is not functional until near maturity. The conversion of the endosperm is effected by enzyms secreted by the epithelial layer of the scutellum. The conversion proceeds from the proximal end toward the distal end, working more rapidly through the layers immediately beneath the aleurone layer. Cytase and diastase, it is claimed, must both proceed from the scutellum, and the proteclytic ferments most probably owe their origin to the same organ. Small-berried barleys were found to have a greater diastatic power, due to the secreting area being proportionately larger. The efficiency of conversion is said to depend upon the shape and composition of the grain and upon the relative quantity of diastase secreted.

The ideal barley grain, it is claimed, should be broadly oval with a scutellum extending well over the edges of the adjacent endosperm. If large yield of malt is desired, the size of the grain should be large. If diastase is the main consideration, the size of the grain should be smaller.

Direct absorption and assimilation of carbohydrates by green plants, L. KNUDSON (Abs. in Science, n. ser., 41 (1915), No. 10 ps. p. 180).—Confirming the work of Molliard and others (E. S. R., 21, p. 126), the author has found that a variety of plants are able to absorb and assimilate various sugars, including lactose. Lactose was found utilized by vetch, radish, and onion, but not by timothy. For maize the sugars in order of preference by the plant are glucose, levulose, cane sugar, and maltose, while for vetch they are cane sugar, glucose, maltose, and lactose. Experiments on the influence of concentration of sugar, and also of the influence of sugars in enzym production, are said to be in progress.

A preliminary study of the chlorophyll compounds of the peach leaf, H. S. Reed and H. S. Stanl (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 180).— Investigations were undertaken with special reference to the chlorophyll content of peach leaves, the trees producing which were affected by the disease yellows. The chlorophyll compounds were extracted and separated by the use of inactive solvents.

The diseased leaves were found to differ from healthy ones both in the quality and quantity of the chlorophyll derivatives extracted. Among the derivatives found in healthy peach leaves were chlorophyll a, chlorophyll b, phytorhodin, chlorophyllin, phæophytin, phæophorbid, methyl-phæophorbid, methyl-chlorophyllid, phytochlorin, carotin, and xanthophyll. As the disease advanced there was found to be a decrease in the quantity of chlorophyll and chlorophyll derivatives. The diminution of the green series was greater than that of the yellow-brown series,

Studies on lycopin and its relations with chlorophyll, W. Lubimenko (Rev. Gén. Bot., 25 bis (1914), pp. 475-493).—The author has followed up work previously done, partly in association with Montéverdé (E. S. R., 31, pp. 128, 520), investigating herein more particularly the relations of lycopin within plants.

The results of the investigation, the author states, showed a striking coincidence between the physiological conditions favoring the formation of lycopin and lycopinoids and those which favor the decomposition of chlorophyll. He regards them as products of a particular chlorophyll oxidation, occasioned probably by the activity of enzyms.

The absorption and excretion of electrolytes by Lupinus albus in dilute simple solutions of nutrient salts, R. H. True and H. H. Bartlett (Abs. in Science, n. ser., 41 (1915), No. 1048, pp. 180, 181).—A study was made, by means of water cultures, of the behavior of seedlings of L. albus toward distilled water and simple solutions of salts containing ions regarded as essential to the normal nutrition of the higher green plants. The plants were kept in darkness and the absorption of ions from the solution measured in terms of electrical conductivity.

The plants were found to give up their salts to distilled water at a variable rate until death resulted from exhaustion. Solutions of potassium phosphate and potassium chlorid acted essentially like distilled water. In potassium sulphate and potassium nitrate a slight absorption phase was observed in the most favorable concentrations; otherwise the results differed little from those seen in phosphate and chlorid solutions. Sodium chlorid was found to affect permeability and growth essentially the same as potassium nitrate and potassium sulphate. In the most favorable concentrations of magnesium nitrate and magnesium sulphate there was a slight but clearly developed absorption phase, resulting in a net gain of electrolytes to the plant. A net loss took place in the more dilute solutions and in the greater concentrations toxic action developed. In calcium uitrate and calcium sulphate solutions all concentrations studied supported active absorption of electrolytes, and apparently enabled the plants not only to retain the salts already present but also to make net gains from the solutions.

The absorption and excretion of electrolytes by Lupinus albus in dilute solutions containing mixtures of nutrient salts, R. H. True and H. H. Babtlett (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 181).—Under conditions similar to those described above the authors grew seedlings of L. albus in graded solutions of pairs of nutrient salts. The results obtained showed that the gain or loss of the electrolytes by the plants was influenced by the antagonistic action of ions.

The process of anthocyanin pigment formation, R. Combes (Rev. Gén. Bot., 25 bis (1914), pp. 91-102).—Summing up results of recent studies (E. S. R., 31, p. 12\$), the author states that pigmentation is a continuous process. In some cases red is formed from the first; in others the original product is yellow, and it may persist, or it may disappear wholly or partly with the production (from its own body or otherwise) of the red pigment. The greater part of the anthocyanin is thus formed in place, a small portion resulting from the transformation of yellow into red pigment.

Relation of transpiration to the composition of white pine seedlings, G. P. Burns (Abs. in Science, n. ser., 41 (1915), No. 1048, p. 181).—In continuation of work previously reported (E. S. R., 30, p. 726) the author repeated experiments there described and in addition noted the effect of transpiration as influenced by one and two covers of cheese cloth. The seeds were sown in May and the first analysis made of seedlings gathered August 11.

The analysis showed that there was an increase in the percentage of protein and soluble ash through no shade, half shade, to full shade, the highest percentage of ash occurring in the full shade bed where the rate of transportation was very low. The effect of the cheese cloth screens was intermediate between no shade and half shade.

Function of water reserves, L. DU SABLON (Rev. Gén. Bot., 25 bis (1914), pp. 459-473, figs. 4).—An examination of the aquiferous cells and tissues of several plants is said to show that such cells possess a nucleus and a protoplasmic layer in a living state, dead cells taking little part in the storing of water on account of the too great permeability of the walls. This property, however, fits them for taking up or getting rid of water where this is advantageous. Several classes of aquiferous cells are discussed in regard to their special adaptations, some such cells also aiding, supposedly, in the regulation of transpiration.

The translocation of materials in aging leaves, N. SWART (Die Stoffwanderung in ablebenden Blättern. Jena: G. Fischer, 1914, pp. 118, pls. 5).—This is a study of the transfer and transformation of materials, of color changes, and of the relations of these to leaf fall.

It is stated that during the process of leaf coloration a transfer of materials from leaf to stem occurs, also that during this period both plasma and nucleus remain intact in the leaf cells. It is held that death of leaves in a climate characterized either by periodicity or uniformity is regulated chiefly by factors which are apparently internal to the plant itself and which generally show a relation to the age of the plant.

Anatomical structure of roots under abnormal tension, P. Jaccard (Rev. Gén. Bot., 25 bis (1914), pp. 359-372, figs. 7).—The author reports that in the species studied (elm, beech, ash, etc.), roots developing under unusual tensions are characterized by a greater development of the conducting system, by alterations in tissue structure and lignification, by changes in the proportion of woody parenchyma and medullary rays, and by an altered diameter, usually of woody elements, also their more regular arrangement and their longer persistence in the living state. It is thought that these may be correlatives of a more general and fundamental reaction to the conditions brought about by tension.

Effects of compression on root structure, M. Molliard (Rev. Gén. Bot., 25 bis (1914), pp. 529-538, pls. 2, figs. 7).—The internal changes produced in small roots by their growth under compression between the lamine of schistose rock in subsoil, are described, those noted in Carlina corymbosa and Enauthe crocata being taken as fairly typical.

Cells developing under pressure are of inferior size. Living elements usually undergo relatively slight deformation, dead cells being much flattened. The elements of wood and bast develop generally parallel to the compression plane, the vessels also being much flattened. The secretory ducts do not differentiate normally, as the fibrous elements are partly or totally suppressed. Hyperplasia is noted at the extremities of the major transverse axis of the root.

Deformation of heath on the seashore, H. Devaux (Rev. Gén. Bot., 25 bis (1914), pp. 133-149, figs. 5).—This contribution on the causes of bushiness deals with the phenomena studied in case of Erica vagans on the seashore, analyzing the direct and indirect effects of wind on growing portions and the responses of the plant as regards production, thinning, bending, and death of the shoots.

Monstrosities of germination in cauliflower and Savoy cabbage, M. Dubard and A. Urbain (*Rev. Gén. Bot.*, 25 bis (1914), pp. 203-216, figs. 6).—The authors have followed up work previously reported (E. S. R., 29, p. 629) by removing

one or both cotyledons of cruciferous seedlings 10 days old. The resulting anomaltes of development, external and internal, are described.

Injury to vegetation by coal tar and other vapors and protection therefrom, R. Ewber (Zlsche, Pflantenkrank., 24 (1914), Nos. 5, pp. 257-273; 6, pp. 321-340, figs. 14).—The author gives a detailed account of the injury to vegetation due to the deposit and absorption of air-borne products from chemical works of various kinds at several points in Germany, with lists of plants found to be susceptible or resistant to these substances.

These effects, although not entirely uniform, are said to be easily distinguished by both external and internal indications from injury by smoke-borne products. A peculiar lacquered appearance was produced on the upper surface of the leaves of a number of economic plants, also frequently a rolling and crinkling of the laminæ. Some showed discoloration over part or all of the surface, accompanied by the formation of a superficial cork layer. Fruit trees showed a decrease of product, and vegetables from this neighborhood (usually within 1,000 meters) quickly lost their turgor and fresh appearance when gathered for market. The production of these effects varied somewhat with the wind and precipitation or differences in the materials discharged.

Experiments under controlled conditions during three years, and in part already confirmed by those of 1914, gave generally similar results which are detailed. It appears that the degree of injury depends not alone upon the amount of materials present in the atmosphere but also upon heat or insolation and dryness. The lacquered appearance followed exposure after one or two days, and it was here also confined to the upper leaf surface. Spraying with water before exposure to the emanations did not protect the plants from injury. Blooms of fruit trees were injured by the presence of the products. Spraying with Bordeaux mixture of 0.5 per cent strength appeared more harmful than otherwise, a result contrasted with that previously noted under other conditions (E. S. R., 28, p. 247). The glossy appearance of the upper leaf surface seems to be at least partly due to the drying out, thinning, and flattening of the epidermal cells. In some cases a superficial cork layer was formed.

The precise chemical and physical action of these emanations is not yet settled. Interference with the protective functions of the epidermis is a probable element, as plants suffer more in dry and sunny weather, with a degree of recovery in shade and moisture which appears, however, to be greater than it really proves to be in the end.

Studies on smoke injury to vegetation in Ratibor-Plania, R. Otto (Ber. K. Lehranst. Obst. u. Gartenbau Proskau, 1913, pp. 116-118).—This is a brief discussion of the studies noted above.

The pathological action of tar on plants, F. von Gabnay (Centbl. Gesam. Forstw., 39 (1913), No. 11, pp. 497-504).—The author gives a brief account of injury to trees by tar used on the trunks as protection against the ascent of caterpillars. It is said to have involved not only the cambium but also the sap wood, extending also beyond the edges of the tarred area. This injury is ascribed largely to the exclusion of air, but partly also (as in case of injury to roots of trees standing near streets paved with wood blocks) to the action of salts and acids. Reports and views of other observers are also discussed.

The vegetation of south Florida, J. W. Harshberger (Trans. Wagner Free Inst. Sci. Phila., 7 (1914), pt. 3, pp. 189, pls. 11, figs. 2).—This is a monograph on the vegetation of Florida south of 27° 30′ N. (exclusive of the Keys), dealing with the geography, physiography, geology, and phytogeography of this region, giving lists of plants as found in the various associations or formations, and concluding with a floristic and ecologic analysis of the region and a discussion of the evolution of each of the formations noted.

FIELD CROPS.

Forage plants and their culture, C. V. Piper (New York: The Macmillan Co., 1914, pp. XXl+618, pls. 8, figs. 62).—This book, one of the Rural Text-Book Series, treats of the different species of plants that have been or may be grown in different parts of the United States. It includes chapters treating of the general subjects of preservation of forage, choice of forage crops, seeds and seeding, and meadows and pastures, and on the special subjects of the species of grasses, legumes, root crops, and miscellaneous herbs used as forage.

[Report of] department of agronomy (Oregon Sta. Rpt. 1913-14, pp. 24-26),—Trials of vetches have shown that smooth vetch (Vicia sativa) is superior to others for western Oregon. In corn breeding Minnesota 13 for silage and forage and Minnesota 23 for grain have, by selection, been made to meet Oregon conditions, yields ranging from 7.4 to 22.1 tons of silage and from 34 to 85 bu. of grain per acre, respectively, having been secured. Variety tests of soy beans, potatoes, wheat, oats, and barley are noted, as in the production of a superior quality of kale seed secured by selection. Thousand-headed kale is noted as being superior to marrow cabbage.

Extensive irrigation experiments covering six years are noted. "A careful study of the effect of irrigation on the soil itself shows that with careful handling as to crop rotation, cultivation, and judicious use of water the quality of the soil may steadily be improved, but with careless handling the quality may be greatly injured.

"Using one dollar, which the data show is the maximum total annual cost for each acre inch, corn has given an average profit of 50 cts, an acre inch, kale 75 cts., beets \$1.18, alfalfa \$1.75, beans \$2.86, clover \$2.87, carrots \$3.74, and potatoes \$7.63 for each acre inch of water applied. The mean profit for each acre inch as an average of all crops and including nearly 150 trials has been \$2.33. The average increase in yield by crops has been 54 per cent and the average depth of irrigation for each season 4.8 in."

Unsuccessful attempts at rice growing are noted.

The relation between the physical characteristics of soils and their grain-producing power, G. Stempel (Landw. Jahrb., 46 (1914), No. 3, pp. 367-401, figs. 6).—After reviewing the literature on this subject, the author gives in tabular form results of the production of oats, barley, and rye on many kinds of soil in Bohemia that have been analyzed. These figures were compiled from the report of the experiment station at Tabor.

Fertilizers and the production of cereals, Palladius (*Prog. Agr. y Pecuario*, 20 (1914), Nos. 878, pp. 452-456; 879, pp. 472-474; 880, pp. 487-490; 881, pp. 503-506; 882, pp. 519-521, figs. 8).—In this article the author points out the relation of yields of cereals to the consumption of potash in the chief grain-producing countries of Europe, and gives results of tests carried on at various centers in Spain that show increased yields following the use of fertilizers, and especially the addition of potash to nitrogenous and phosphatic fertilizers for wheat, barley, oats, and rye.

The small grains in Tennessee, C. A. Mooers (*Tennessee Sta. Bul. 112* (1915), pp. 9-30, figs. 9).—This bulletin gives results of variety tests of wheat, barley, and oats covering a period of several years.

It is noted that the best varieties of wheat for Tennessee conditions were Kansas Mortgage Lifter and Fulcaster. In studying methods of selection for improvement it is shown "that the Poole [variety of] wheat could be separated into strains or varieties which had different yielding capacities. The continued selection of the largest and best heads resulted in a variety which yielded highest and was markedly different in general appearance from the variety

obtained by selection of the most inferior heads, . . . The results with the Fulcaster variety show that no difference in yield was obtained by either method of seed selection, . . . Also efforts to separate out strains by individual plant selections were without result. In short, the Fulcaster variety used in these experiments must have been a pure strain which was not capable of being changed by any of the methods used."

Winter barley is noted as being a useful crop for Tennessee, the varieties Tennessee and Union being the best yielders. Better yields were obtained with seeding the latter half of September. Red clover is noted as being successfully sown with early-seeded winter barley and winter oats. Spring barley has proved inferior to spring oats, but may be used as a nurse crop. Better yields of winter oats were obtained from September seedings than from later seedings. Spring oats were successfully sown with Kentucky blue grass in the fall as a protection for the young grass, as they winter-killed and were out of the way for the full development of the grass in the spring.

Turf, C. M. Huteninson (Agr. Jour. India, 9 (1914), No. 4, pp. 366-383, pl. 1).—This article describes various treatments of lawns, both manurial and cultural. Cynodon dactylon seems to have been the most successful grass as a turf former. The successful application of sand at the rate of 150 lbs, to 100 sq. ft. of lawn, on soils that were inclined to bake or crack during dry weather, is noted.

Grading and baling Philippine fibers, H. T. EDWARDS (Philippine Agr. Rev. [English Ed.], 7 (1914), No. 10–12, pp. 381–390, figs. 5).—This article describes the official standard grades, gives methods of determining them, and describes the baling and labeling of fibers as required in the fiber industry of the Philippines.

Description of the standard grades of abacá (Manila hemp), M. M. SALEEBY (Philippine Agr. Rev. [English Ed.], 7 (1914), No. 10-12, pp. 402-410).—This article gives specific descriptions of each grade of the newly established standard for abacá for the Philippines. These descriptions are based upon color, cleaning, texture, and length, and include brown, seconds, current, midway, good current, superior current, prime, and extra prime.

The rejuvenation of depleted abacá fields, F. P. Nickles (Philippine Agr. Rev. [English Ed.], 7 (1914), No. 10-12, pp. 411-419, pls. 2).—This article describes improved methods of cultivating abacá that have been successfully tried at the La Carlota station and by some growers. These methods consist chiefly of clean cultivation and the use of cowpeas as a cover and greenmanure crop.

Alfalfa farming in America, J. E. Wing (Chicago: Sanders Publishing Co., 1912, pp. 528, pls. 20, figs. 5).—A treatise on the production and uses of alfalfa with special reference to the United States.

Alfalfa culture, P. J. Jennings, R. J. Burley, and W. H. Fairfield (Dept. Int. Canada, Irrig. Ser. Bul. 2 (1914). pp. 26. pls. 2, figs. 3).—This bulletin gives the results of successful attempts to grow alfalfa, especially under irrigation, in Alberta and Saskatchewan.

Alfalfa, W. T. CLARKE (California Sta. Circ. 87, Reprint, pp. 6).—The article previously noted (E. S. R., 29, p. 32) has been rewritten.

Fertilizer experiments with beans in the valley of Mexico, M. Calvino (Bol. Soc. Agr. Mexicana, 38 (1914), No. 42. pp. 824–827. fig. 1).—This article describes a fertilizer experiment with beans in which the addition of 80 kg. per hectare (71.2 lbs. per acre) of sulphate of ammonia to a fertilizer consisting of sulphate of iron 100 kg., double superphosphate 80 kg., sulphate of potash 80 kg., and gypsum 260 kg., per hectare, produced an increase of 356 kg., and a total yield of 1.880 kg., of beans per hectare.

Bur clover seed; means of hastening their germination, J. F. Duggar and H. B. Tisdale (*Alabama Col. Sta. Circ. 29 (1914*), pp. 113-116).—This describes several methods of soaking and scalding seed burs of bur clover to hasten germination.

The most successful method was found to be that of soaking for four hours in water at room temperature and then scalding for one minute in boiling water (212° F.). In nine days 76 per cent of burs germinated by this method as against 8 per cent with neither soaking nor scalding. Directions for soaking large amounts of seed are included.

On the relation of the anatomical coefficients of maize to its heights and the nitrogen content of the kernel, S. Moskylchev (Zhur. Opyth. Agron. (Russ. Jour. Expt. Landw.), 15 (1914), No. 4, pp. 266–281).—In an examination of five varieties of maize, the data obtained in measuring the stoma of the upper and the fifth leaf (15 samples from each variety), the height of the plants, and the nitrogen content led to the conclusion that with an increase of cell size the height increased and the nitrogen content sank.

Effect of the submersion of corn, E. Marchettano (Coltivatore, 60 (1914), No. 32, pp. 433-435, figs. 2).—This notes the abnormal development of the male and the female parts of maize as results, apparently, of planting in the submerged alluvial soils of Lower Friuli, where soil may be covered with water to a depth of from 15 to 20 cm. (5.6 to 8 in.) for several days.

Fertilizer experiments with maize, M. Calvino (Bol. Cámara Agr. Nac. Leon, 4 (1915), No. 1, pp. 4-8).—This article describes experiments and gives results showing the value of bone meal, sulphate of potash, gypsum, sulphate of ammonia, and double superphosphate as fertilizers for maize in Mexico. It is noted that the increase in yields has returned from 200.65 to 321.55 per cent interest on the cost of the fertilizers in six months in these experiments.

The modern cultivation of corn, Z. Dominguez (San Antonio, Tex.: Dominguez Corn Book Publishing Co. [1914], pp. 351, pls. 4, figs. 249).—An English edition of the Mexican book entitled Agricultura, already noted (E. S. R., 32, p. 131).

Cotton cultivation in the West Indies, W. Nowell and H. A. Ballou (Imp. Dept. Agr. West Indies Pamphlet 74 (1914), pp. 118, pl. 1. figs. 35).—Cultural methods are described.

[Cotton experiments], G. G. Macdonald (Rpts. Finance, Admin., and Condition Sudan, 1913, vol. 2, pp. 143-151).—This report gives results of variety tests which show some American varieties to surpass the ordinary Egyptian varieties at the Tokar experimental farm. Spacing tests showed 70 by 80 cm. (27.6 by 31.5 in.) to be the most favorable spacing for the Assili type and 90 by 100 cm. for the Affifi type. Pruning plants by topping those that showed a tendency to produce wood was found to increase the yield considerably.

Preliminary work with hybrids of cotton, J. Herrmann (Bol. Agr. [Sao Paulo], 15. ser., No. 6-7 (1914), pp. 559-578, figs. 8).—This discusses preliminary work and gives data in hybridizing Upland and Caravonica varieties of cotton at the Eliza station.

The influence of some chemical reagents on the sprouting of potato tubers, E. Nicklisch (Untersuchungen über den Einflusseiniger ehemischer Agentien auf die Keimfähigkeit der Kartoffelknolle. Inaug. Diss. Univ. Erlangen, 1912, pp. 51).—This describes experiments and gives the results of the use of sulphuric acid, hydrochloric acid, sodium chlorid, copper sulphate, carbon monoxid, and carbon dioxid.

Tubers were immersed in solutions of these chemicals of concentrations of 0.5, 1, 2, 3, and 4 per cent for periods of 6, 12, 24, and 48 hours. On the basis of his observation of the vegetative conditions of the tubers, the author con-

cluded that the strong solutions of sulphuric acid and of copper sulphate suppressed sprouting for the longer periods, and growth was almost entirely prevented in the hydrochloric acid series. The weaker concentrations of sulphuric acid and hydrochloric acid somewhat retarded sprouting and later development of the sprouts. Carbon dioxid seemed to delay sprouting, but it was hastened by the action of sodium chlorid and carbon monoxid.

Group classification and varietal descriptions of some American potatoes, W. Stuart (U. S. Dept. Agr. Bul. 176 (1915), pp. 56, pls. 19).—In order to aid the student and grower of potatoes, the author has in this bulletin classified known varieties into eleven groups, each named from the most typical well-known variety in the group. A key, describing the tubers, sprouts, and flowers of each group is presented, followed by detailed group descriptions and a list of varieties belonging thereto. Varietal descriptions of varieties, arranged alphabetically, occupy the bulk of the bulletin.

Improvement of the seed potato, G. Martiner (Ann. Agr. Suisse, 15 (1914), No. 2, pp. 242-253, figs. 10).—This article notes variations due to apparent grafting of underground stocks and to selections.

Utilization of potatoes in Europe, R. P. SKINNER (U. S. Dept. Com., Spec. Cons. Rpts., No. 64 (1914), pp. 8-15, 18, 19, 33-44).—These pages contain data compiled from reports of consular officers in European countries, especially Germany, showing the development of the potato industry and the value, costs, and uses of products manufactured from potatoes, starch, alcohol, and dried potatoes. Reference is made to the opportunities of American farmers in manufacturing potato products.

On the pollination and crossing of rice, S. Ikeno (Ztschr. Pflanzenz"ueht., 2 (1914), No. 4, pp. 495–503. figs. 2).—This article discusses the method of opening of the rice flower, and notes observations confirming the work of earlier investigators that rice seldom, if ever, cross-pollinizes in nature. The results of reciprocal crosses between a variety of common rice and one of a glutinous type show the colors and endosperm characters to mendelize in the F_2 generation.

The correlative relations of the internodes of a stalk to itself and the determination of the stalk structure as a guide in selection of nonlodging cereals, demonstrated with rye, H. Plahn-Applani (Ztschr. Pflanzenzücht., 2 (1914). No. 4. pp. 461-494, figs. 2).—This article gives the results of tests of bending and breaking stresses of rye straw in full lengths and in internode by internode lengths.

[Soy beans], N. Gill (Ann. Rpt. Kumaun Govt. Gardens, 1913-14, pp. 2-4).— This article gives the results of tests with several varieties of soy beans on soils, the chemical and physical analyses of which are given. The data show yields, oil percentage, moisture, ash content, and weight of 100 seeds.

Spacing experiments in sugar beet cultivation in Hungary in 1913, B. von Jancsó (Österr. Ungar. Ztschr. Zuckerindus. u. Landur.. 43 (1914), No. 5, pp. 685-694).—Reports from 16 centers at which beets were spaced 8 and 10 in. apart in rows spaced from 14 to 18 in. apart showed the most favorable results by spacing 8 by 14 in., as compared with 10 by 14 in. the preceding season (E. S. R., 31, p. 334). It is noted, however, that 8 by 16 in. and 10 by 14 in. gave nearly as good results as the 8 by 14 in. It is stated that this was a very favorable season for the development of the sugar beet in Hungary.

Drilling fertilizer experiments with sugar beets in Hungary in 1913, J. Gyárfás (Österr. Ungar. Ztschr. Zuckerindus. u. Landw., 43 (1914), No. 5, pp. 675-684).—This continued previous work (E. S. R., 30, p. 529; 32, p. 230) and with similar results. The effect of drilling superphosphate and nitrate of soda,

combined and singly, was to increase germination of beet seeds and hasten early development. The superphosphate seemed to improve the root development and the nitrate the leaf development.

[Seedling canes and manurial experiments], J. P. r'Albuquerque and J. R. Bovell (Barbados Dept. Agr., Rpt. Sugar-Cane Expts. 1912-1914, pp. 4-82).—This reports the progress of work in manurial experiments and variety tests with seedling canes, previously noted (E. S. R., 30, pp. 340, 835).

It is noted "that all the plats that received sulphate of ammonia gave an increase over the no-nitrogen plats, and that the most favorable result of the application of nitrogen in any form was obtained on the plat that received 60 lbs, of nitrogen as sulphate of ammonia, 15 lbs, in January and 45 lbs, in June. The plats receiving nitrogen as dried blood, to the extent of 40 or 60 lbs, nitrogen, with one anomalous exception showed an increase on the no-nitrogen plat, but not so great as in the best sulphate of ammonia plats. The results of the nitrate of soda plat must be rejected as unreliable. The results of the phosphate series show that all the plats that received phosphate either in the form of superphosphate or basic slag, gave smaller yields than the no-phosphate plats. With two exceptions all the potash plats show an increase on no-potash and the best result of the series was given by the plat that received 80 lbs, of potash as sulphate of potash (about 160 lbs, sulphate of potash) applied all in January."

Results of productivity tests of artificial hybrids, natural hybrids, self-fertilized seedlings, seedlings obtained from selected seeds, and varieties of ration plantings carried out at many centers on both black and red soils, are given in tabular form. It is noted that variety B. 6450 has as usual given satisfactory results in comparison with the standard White Transparent. The average yield of this variety over the standard, both plants and rations on black and red soils, is given as 6.5 tons of caues per acre for the season 1912–1914.

[Fertilizers on sugar cane], H. T. EASTERBY (Ann. Rpt. Bur. Sugar Expt. Stas. [Queensland], 1914. pp. 30, 31).—Experiments with different forms of nitrogenous manures, including dried blood, sulphate of ammonia, nitrolime, nitrate of ammonia, and nitrate of soda, applied to sugar-cane plant crop at the rate of 100 lbs. of nitrogen per acre, gave 8.5, 7.9, 7.8, 7.4, and 7.3 tons of sugar per acre, respectively.

Experiments and observations on Helianthus annuus, F. A. Satsyperov (Trudy Būro Prīkl. Bol. (Bul. Angew. Bot.), 7 (1914), No. 9, pp. 543-600, figs. 2).—This discusses work with the sundower of Russia carried on during 1912, 1913, and 1914 at the experiment station in the Government of Voronezh. Notes cover the development of the stem, leaf, inflorescence, flower, fruit, and abnormalities. Some work is described in the inheritance of the characters of armored layer of cells beneath the subepidermal tissue, black-violet pigment in the subepidermal tissue, and the pigment in the epidermis which gives the seeds a striped appearance.

Sweet clover, C. C. Cunningham (Kansas Sta. Circ. 44, pp. 10, figs. 3).—This gives cultural methods and uses.

Sweet clover, I. S. Cook (West Virginia Sta. Circ. 14 (1915), pp. 7, figs. 5).— This gives cultural methods and uses of this plant under West Virginia conditions.

Deli tobacco, a mixture of races, based on differences in leaf-breadth, J. A. Honing (Meded. Deli-Proefstat. Medan, 8 (1914), No. 6, pp. 155-174).—This article gives measurements of tobacco leaves from the harvest of 1913 and 1914 from differently bred lines of Deli tobacco and discusses the results.

Report on experiments on the manuring of turnips in 1909, 1910, and 1911, J. WYLLE (West of Scot. Agr. Col. Bul. 60 (1912), pp. 17-39).—This reports results in testing commercial fertilizers for turnips in the central and southwestern counties of Scotland. The following conclusions are given:

"Where farmyard manure is not applied, the use of both potassic and nitrogenous manures for turnips is to be recommended, but of the two the former are more essential and more likely to yield high money returns. Kainit and potash manure salts are about equally efficacious. . . .

"The relative efficacy of $\frac{1}{2}$ and 1 cwt, nitrate of soda as a top-dressing, along with $\frac{1}{2}$ cwt, sulphate of ammonia in the drills, varies very much, and the chances are slightly in favor of the $\frac{1}{2}$ cwt, dressing proving the more economical. Contrary to popular opinion, $\frac{1}{2}$ cwt, nitrate of soda in the drills gives, in the majority of cases, a better result than $\frac{1}{2}$ cwt, top-dressed, the chances being about 3:2 in favor of the drill application. Also, $\frac{1}{2}$ cwt, nitrate of lime in the drills gives, in the majority of cases, a better result than a similar amount top-dressed.

"As a top-dressing for turnips, nitrate of lime is at least equal, and in many cases the superior, of nitrate of soda. For drill application, nitrolime is, on the average, about equally efficacious to sulphate of ammonia [and nitrate of lime].

"The best nitrogenous dressing for turnips varies very much according to local conditions."

Correlation and variability relations in a constant square-head variety of wheat, W. Oetken (Ztschr. Pflanzenzucht., 2 (1914), No. 4, pp. 445-460, figs. 2).—To study these relations in practical breeding, the author considered the characters, length of stalk, stooling, thickness of spike, and 1,000-kernel weight as they appeared in the first generation from selections of extremes of these characters. From the data obtained, he was forced to admit his inability to formulate any general ratios of correlations or variabilities.

The flowering and pollination of some forms of spring wheat, T. Shitkowa (Zhur. Oputa. Agron. (Russ. Jour. Expt. Landur.), 15 (1914), No. 3, pp. 155–180).—The results of the study, during 1912 and 1913, of varieties of wheat representing the forms Lutescens, Erythrospermum, Hordeiform, and Graecum in regard to the opening of the flowers and anthers, show a wide variation in different seasons, due, apparently, to climatic conditions, and also in the time of day of the same variety, often causing failure in pollination. The author concludes, therefore, that the different forms of the same agricultural plant behave very differently in regard to their flowering and pollination and that any one kind must be handled with extreme care.

Spacing, depth of seeding, and tillering in spring wheat, O. D. RABOMNOVA (Zhur. Opytn. Agron. (Russ. Jour. Expt. Landuc.), 15 (1914). No. 5. pp. 371–394).—Two varieties of spring wheat, Triticum vulgare erythrospermum and T. durum hordeifome, were spaced to have 12.5, 25, 50, 100, and 200 sq. cm, per plant (1 sq. cm.=0.155 sq. in.). Yields per plant were found to be largest when grown in the largest space, but the quality of the grain was considered inferior. Per surface unit, however, the reverse was observed. The best spacing for T. durum seemed to be 100 sq. cm. and for T. vulgare 12.5 sq. cm.

In studying the influence of depth seed was planted 2 (0.787 in.), 4, 6, 8, and 10 cm. The best germination was secured at the most shallow depth. Tillering was found to begin later with the deeper plantings, but the growth period was shorter so that all heads matured uniformly. No difference in yield was observed at the different depths, but the shallow-planted seeds produced grain of greater 1.000-kernel weight. At the 2-cm, depth the tillering nodes were formed at the seed, while at greater depths these nodes were formed

above the seed and near the surface of the soil. The seeds planted 10 cm, deep are noted as having three tillers.

Wheat production in Georgia, J. R. Fain and P. O. Vanatter (Ga. State Col. Agr. Circ. 6 (1914), pp. 4).—This circular notes the production of wheat in Georgia. The results of tests from 1909 to 1914 show yields ranging from 18.33 to 32.91 bu, per acre with an average of about 25 bu.

Washington wheats, E. G. Schafer and E. F. Gaines (Washington Sta. Bul. 121 (1915), pp. 3-16, figs. 2).—This bulletin describes fifteen varieties of wheat grown in Washington, and gives yields of field and nursery tests of numerous varieties for the years 1911, 1912, and 1914. Tables show the percentage of flour produced and of wet gluten, dry gluten, and nitrogen contained in the wheats studied.

The best variety in the test as to both yield and quality is noted as being Hybrid 128, a cross between Jones Winter Fife and Little Club. The average yield for this variety for the three years mentioned was 43.8 bu, per acre.

Nitrogen content of the wheats of southeastern Russia, N. Tulaikov (Iuzh. Russ. Sclsk. Khoz. Gaz., No. 9 (1913), p. 6; abs. in Zhur. Opyta. Agron. (Russ. Jour. Expt. Landw.), 14 (1913), No. 4, p. 401).—This article gives results of experiments that indicate the influence of the concentration of the soil solutions as affecting the nitrogen content of wheat. It is stated that by increasing the soluble salts, but not changing the moisture content in the soil in which the wheat was grown, the nitrogen content of the grain was increased considerably.

A new sterilization stopper and method of storing seeds by the use of wire gauze and cotton. M. Plaut (*Ber. Deut. Bot. Gesell.*, 32 (1914), No. 7, pp. 466-471, figs. 3).—A method is described for covering glass bottles or other containers with a layer of cotton under wire gauze to allow for aeration in storing seeds.

Seed inspection (Maine 8ta. Off. Insp., 64 (1914), pp. 153-164).—The chief requirements of the Maine seed-inspection law are given, methods for testing seeds at home are described, and results of seed inspection for 1914 are given in tabular form showing nearly 1.300 samples as being practically up to the guaranty of purity.

Forty years of seed-control work, M. Heinrich (Landw. Vers. Stat., 85 (1914), No. 3-4, pp. 269-357, pl. 1).—This article reviews the work of the seed-control station of Rostock, giving tabulated data and discussions of important species handled since 1874, when 116 seed samples were examined. The number in 1913 reached 3.028.

Thirty-sixth report of the Swiss Seed Control and Experiment Station at Zurich, F. G. Stebler (*Landw. Jahrb. Schweiz*, 28 (1914), No. 2, pp. 187-209).—This gives the results of seed examinations of 12,702 samples from 199 kinds, and briefly reviews the experimental work with field crops.

Weeds of barley fields in the forest area of European Russia, A. I. Maítsev (Trudy Biuro Prikl. Bol. (Bul. Angew. Bol.), 6 (1913), No. 12, pp. 825-962).—This discusses the immense damages to the barley industry caused by weed seeds, and lists and describes the different weeds of several Governments of European Russia, giving results of analyses of samples that show the percentage of weed seeds by weight and by number.

HORTICULTURE.

How to send living plant material to America, D. FAIRCHILD (U. S. Dept. Agr., Bur. Plant Indus., How to Send Living Plant Material to America [1914], pp. 3, pls. 6).—This circular contains directions with illustrations of the proper

methods of preparing seeds, cuttings or scions, and rooted plants for shipment to America with the view of avoiding the dangers of introducing diseases and to insure arrival of the material in a vigorous growing condition.

The use of hotbeds and cold frames on the farm, A. L. Davy (West Virginia Sta, Circ. 13 (1915), pp. 16, figs. {).—The author points out the advantages of hotbeds and cold frames, and gives directions for their construction and management.

The farmer's vegetable garden, H. O. Werner (North Dakota Sta. Circ. 5 (1915), pp. 18, figs. 4).—A popular treatise on vegetable gardening with special reference to the production of a home supply. In addition to general cultural directions brief notes are given on the culture of the more common vegetables, including information on storing and canning.

The results of variety tests of early, midseason, and late cabbage during 1914, together with a planting table for North Dukota conditions, and a short bibliography of literature on vegetables are appended.

Inheritance and selection by vegetative propagation of garlic (Allium sativum), P. Vogler (Jahrb. 8t. Gall. Nature, Gesell., 53 (1913), pp. 102-146, figs. 9).—The principal results of this investigation have been noted from another source (E. S. R., 30, p. 738). In addition, the author here concludes that selection within a strain based on plus or minus variants is of no value. Modified characters are not inherited through vegetative propagation.

Orchard and garden spraying, H. L. Crane (West Virginia Sta. Circ. 12 (1914), pp. 4).—This comprises a spray calendar for the treatment of the more common insect pests and diseases of fruits and vegetables, together with instructions for preparing solutions.

Spraying calendar for 1915, A. L. MELANDER and D. C. George (Washington Sta. Popular Bul. 77 (1915), folio).—This calendar contains concise descriptions of the pests and diseases of various orchard fruits, together with instructions for their treatment. Information is also given relative to the preparation of different solutions.

[Report on the] section of fruit breeding (Minnesota Sta. R_Pt . 1914, pp. 37-40).—In the section of fruit breeding special emphasis was given during the season to the study of inheritance in clonal varieties. The results thus far secured, here briefly stated, show that the inheritance of characters in the F_1 generation in clonal varieties of plums is not constant, as is ordinarily expected in Mendelian phenomena. The results to date of the sterility investigations with strawberries and plums show that the nuclei of mature pollen in both the plum and strawberry are abnormal, degenerated, and disorganized in many of the sterile or partially sterile varieties. Careful study is being made of the plum hybrids at the fruit breeding farm. These include crosses between several species such as $Prunus\ triflora\ \times\ P.\ americana\ P.\ besseyi\ \times\ P.\ americana\$, the apricot \times sand cherry, $P.\ simonii\ \times\ P.\ triflora\$. As thus far observed some of the hybrids between $P.\ americana\$ and $P.\ triflora\$ appear to be self-sterile.

A special study has been made of the general question of hardiness in fruits. The percentage of winterkilling in strawberries, based on observations of several hundred different crosses during the previous winter, varied from a perfect stand to as high as 60 per cent. Most of the varieties stood the winter well, but there was a marked difference in the percentage of killing under practically similar field conditions. Some of the crosses between *P. americana* and *P. triflora* have proved hardy, and ceratin of the crosses between the Burbank and Wolf and the Abundance and Wolf have proved sufficiently hardy to suffer no injury from winters such as 1911–12. The results of the hardiness tests of these hybrids show in general that when a semihardy variety is crossed with a hardy variety the progeny inherit resistance to cold in different de-

grees. A list is given of new plums, grapes, raspberries, and strawberries that have been produced in connection with the work of breeding hardy fruits and have been sent to the trial stations for testing.

Pruning, O. M. Morris (Washington Sta, Popular Bul. 79 (1915), pp. 32, figs. 42).—In part 1 of this bulletin the author gives directions for pruning various fruit trees, the subject matter being based upon a study of pruning practices employed by the successful fruit growers of the State. Part 2 discusses the fundamental principles involved in the more common pruning practices, consideration being given to the influence of pruning on growth, heavy pruning of the top, pruning the roots, pruning trees to shape the top, variety types, pruning to induce fruit production, season of pruning, treatment of wounds, ties, and props.

Effect of various dressings on pruning wounds of fruit trees, G. II. Howe (New York State Sta. Bul. 396 (1915), pp. 83-94).—Experiments were started at the station in 1911 and conducted for four years to determine whether any coverings are necessary for wounds of trees, as well as the effect on the trees of various substances used in treating wounds. The trees used in the experiments were apples and peaches and the substances used as coverings were white lead, white zinc, yellow other, coal tar, shellac, and avenarius carbolineum. The dressings were applied when the pruning was done at different seasons of the year and upon wounds of various ages.

From the results of this experiment as a whole it is concluded that the dressings commonly applied to pruning wounds retard rather than accelerate the healing of the wounds. The effects are the same whether the dressings are applied when the wounds are made or some weeks later when the cut surface has dried out. The effects of the dressings used are so injurious to peach wood that wounds on peach trees should never be covered. For sprayed orchards at least it appears unnecessary to apply dressings to wounds under four or five in. in diameter to prevent the entrance of fungi. It remains to be proved whether dressings have any real value in covering large wounds. The injury caused by dressings probably offsets or even overbalances any possible protection against decay.

Of the materials used shellac was the least injurious and seemed to exert a stimulating influence upon the wounds for the first season. Shellac adhered to the wounded surfaces least well of all. Avenarius carbolineum and yellow ochre caused so much injury that they should never be used as dressings. Coal tar in addition to causing injury disappeared rapidly, either through absorption or evaporation. Tissues injured by using white lead and white zinc practically recovered from the injury by the end of the second season. Of the protective substances used white lead is considered to be the best.

Pruning wounds need no protection, F. H. HALL (New York State Sta. Bul. 396, popular ed. (1915), p. 1).—A popular edition of the above.

Soils of Massachusetts and Connecticut, with especial reference to apples and peaches, H. J. Wilder (U. S. Dept, Agr. Bul. 140 (1915), pp. 73, pls. 23).— In this bulletin the author gives a general description of the surface features, soil material, and climate in different parts of southern New England. The development of orchards on suitable soils and the kinds of soil on which several of the different varieties of apples and peaches may be expected to give favorable results are then discussed in some detail. Considerations are given to cultural methods in orchards, the usual type of farm-orchard development in Massachusetts and in western New York, relative production of apples in southern New England, relation of soil characters to crop and varietal adaptation, the adaptedness of soils to different varieties of apples, classifica-

tion of soils, miscellaneous notes on soil-varietal adaptation, and the adaptedness of soils to varieties of peaches.

Eliminating unprofitable trees from the apple orchard, S. W. FLETCHER (*Proc. Amer. Pomol. Soc.*, 1913, pp. 138-145).—To show the importance of keeping a yield record for orchard trees the author gives the results secured from a record of an apple orchard kept for a period of four years.

Of a total of 1.245 trees 375 trees averaged 4 bbls, per tree annually and produced 60 per cent of the crop. Two hundred and fifteen trees produced less than 1 bbl, per tree annually each and had been kept at a loss.

Further experiments in the dusting and spraying of apples, D. Reddick and C. R. Crosby (New York Cornell Sta. Bul. 354 (1915), pp. 53-96, figs. 24).—The work reported in this bulletin is in direct continuation of that previously reported by Blodgett (E. S. R., 30, p. 840).

The experiments were conducted on a commercial scale in three different orchards. Comparisons were made between the dry mixture of sulphur and lead arsenate, lime-sulphur solution, and lead arsenate, and no summer treatment. Details as to quantities of material used, dates of application, and conditions influencing the same, time required, comparative costs, results, and methods of recording data are given in connection with the individual experiments.

Among the important points brought out by the present work the dust method seems to be particularly applicable to large old trees with which the difficulty in doing thorough spraying is most apparent. Although the efficiency of the dust spray in controlling the apple-scab fungus varied in the different orchards, the authors conclude that this is due more to the time of application in connection with prevailing weather conditions than to the lack of efficiency of the mixture. The results obtained in one orchard at least were as favorable in controlling apple scab as those previously reported by Blodgett. Mechanical difficulties in connection with the dusting processes have been sufficiently removed to secure more reliable cost data, and it now appears that an orchard may be protected by dusting as cheaply or even cheaper than by spraying. sects were not prevalent during the year; hence the tests of the various mixtures on insect control gave no decisive results, except that it appears that the dust mixtures containing 10 per cent of arsenate of lead are as effective as those containing twice the amount. A test of different quantities of dry sulphur per tree indicates that for the present it would be advisable to use a mixture of 90 parts of pure sulphur, especially finely ground, and 10 parts of powdered arsenate of lead, applying on an average 1.5 to 3 lbs. of the mixture per tree at each application.

It was sought to determine whether the adhesive properties of the dry mixture might be improved by the addition of an inert substance. Of the substances used neither gypsum nor wheat flour added to the adhesiveness materially, and the expense of the wheat flour practically precludes its use. Apparently good results were secured in one orchard by mixing hydrated lime with the sulphur. It is suggested, however, that this may have been due to an application of Bordeaux mixture or to applications of dust mixture under very favorable conditions. Prepared sulphur paste suspended in water was compared with lime-sulphur solution; but the test, although not conclusive, indicates that the sulphur paste is not so effective as the lime-sulphur solution.

Among other points brought out by the work, it appears that the amount of secondary infection may be materially reduced by the early destruction of fallen leaves subsequent to the primary infection. Plowing under the old leaves, however, will not be sufficient to make the application of fungicides unnecessary. Observations relative to the factors influencing the adhesiveness

of the dust mixtures indicate that this may be due partially to the fact that the particles of the dust mixture are fine enough to lodge in the dense mat of fine plant hairs covering the leaves and partially to the adhesive nature of some of the lead compounds. Generally speaking, the time of application of dust does not differ from that of applying the spray, except that dusting may be conducted profitably on foggy days subsequent to a heavy early morning rain, whereas spraying could not be done because of wet ground and the drip from the foliage. Under the conditions of the experiments, no inconvenience was experienced from breathing the dust and no unfavorable symptoms of anything like lead poisoning. The eyes should be protected; otherwise no special equipment is necessary.

With reference to the relative importance of dusting and spraying, the authors conclude that in the light of present knowledge the trees must be sprayed in the dormant stage just as in the past. Summer sprayings will doubtless continue in the smaller orchards. Where the orchard is of such an extent that it is practically impossible to keep enough outfits to do the spraying at critical times, the duster will afford necessary relief. In view of the ease with which dust is applied, it appears to be especially applicable to the general farmer with a few trees in the home orchard who rarely ever sprays.

Dusting the apple orchard, D. Reddick (Fruit-Grower and Farmer, 26 (1915), No. 5, pp. 7, 29, figs. 2).—A popular résumé of the experiments made at the Cornell Station in substituting dusting for spraying.

Influence of the axillary shoot on the development and composition of the peach, A. MANARESI and A. DRAGHETTI (Bul. Uffic. Assoc. Ort. Prof. Ital., 3 (1915), No. 1, pp. 8-11).—A comparative study was made of peaches provided with axillary shoots and those not accompanied by axillary shoots during their growth.

The data as here presented indicate that those peaches which are provided with axillary shoots are on the average the heavier, and that the difference in weight is greatest when the tree is vigorous and receives plenty of sunlight. The presence of the shoots somewhat retards the maturing of the fruit. The peaches from trees provided with shoots are less firm and apparently more acid and richer in dry matter.

Native American species of Prunus, W. F. Wight (U. 8. Dept. Agr. Bul. 179 (1915), pp. 75, pls. 13, flgs. 4).—This work contains botanical descriptions of the native American species of Prunus and their hybrids. The subject matter is based on a study of nearly all the species in the field, of more than 400 horticultural varieties, and of the collections of this Department and various institutions throughout the country. Introductory considerations deal with the distribution, variation, and adaptability, early history, early botanical descriptions, and horticultural history and development of American plums. A synopsis and key to the species is then given, after which the species are described in detail with reference to their synonymy, literature, characteristics, distribution, and varieties. A bibliography of cited literature is appended.

Pruning stone fruits, O. B. Whipple (Mo. Bul. Com. Hort. Cal.. 4 (1915), No. 1, pp. 1-7).—A paper on this subject based on the author's personal observations and experience in pruning apricots, sweet and sour cherries, nectarines peaches, and plums. The methods of pruning are discussed with special reference to the maintenance of desirable types of fruiting wood.

Ampelographical studies, J. Marques de Carvalho (Bol. Dir. Geral Agr. [Portugal], 10 (1912), No. 5, pp. 302, figs. 130).—The present work was prepared under the direction of the Portuguese Department of Agriculture and comprises monographs of the varieties of Vitis vinifera. A complete botanical descrip-

tion is given of each variety, together with information relative to its time of maturity, productivity, soil adaptation, uses, disease resistance, relative proportion of pulp and must, and chemical composition of the must and wine made from it. The introductory parts contain a historical résumé of viticulture and a classification of the genus Vitis. A bibliography of cited literature is included

Olive culture and production of olive oil in the southern Provinces of Austria, G. Slaus-Kantschieder (Olivientlura e Produzione d'Oliva nelle Provincie Meridionali Austriache, Spalato, Austria: Tipografia Sociale Spalatina, 1914, pp. 45).—A general descriptive account of olive culture in various Provinces of littoral Austria, including statistics of production for the 12 years ended in 1912 and notes on destructive insect pests and fungus discases of the olive.

The loquat, I. J. Condit (California Sta. Bul. 250 (1915), pp. 251-284, figs. 11).—This bulletin treats of the loquat with reference to its botany and nomenclature; geographic distribution; climatic requirements; propagation; soils and situations; orchard management; harvesting, packing, and marketing; varieties, including descriptions of the more promising forms; and insect pests and diseases. The subject matter is based upon field observations as well as upon an extensive search of the literature. A bibliography is appended.

Manurial experiments on cacao, 1913–14, J. DE VERTEUIL (Bul. Dept. Agr. Trinidad and Tobago, 14 (1915), No. 1, pp. 1-16, pls. 8).—A progress report on the manurial experiments which are being conducted on a number of private estates (E. S. R., 30, p. 444). The results obtained during the year ended August 31, 1914, are given for each estate, together with comparative data for the two previous years.

Data are also given on the natural-yield plats for the last two years,

The results from these plats continue to indicate that the yield tendencies on any particular plat should be well known before manurial experiments are undertaken.

The composition of the coffee berry and its relation to the manuring of a coffee estate, R. D. Anstead (Ann. Appl. Biol., 1 (1915), No. 3-4, pp. 299-302).—In connection with a study of methods of fertilizing coffee in southern India the author found that under well-established mixed shade some four tons of air-dry weight of mulch is accumulated per acre each year, containing 108 lbs. of nitrogen, 223 lbs. of calcium oxid, 36 lbs. of phosphoric anhydrid, and 118 lbs. of potassium oxid. It is concluded that the mulch obtained from shade trees should be taken into account in drawing up a manurial program over a series of years.

During 1912 analyses were made of coffee berries each month from July to December, or from the time they were quite small to the time when they were ripe and ready to pick and pulp. The analyses show that there is a markedly steady increase of potash content throughout the period of growth, from which it is concluded that potash in an available form is needed all the time. The phosphoric acid content appears to be a constant quantity at first with a maximum about October, after which it declines. This suggests that available phosphoric acid is needed chiefly in the beginning of the season. The nitrogen content increases steadily throughout the period of growth and keeps pace with the increase of organic matter. There is a rapid and regular decrease in the amount of moisture in the berries throughout the period of development.

A series of manurial experiments based on these analyses has been planned and is now being carried out.

A new genus, Fortunella, comprising four species of kumquat oranges, W. T. Swingle (Jour. Wash. Acad. Sci., 5 (1915), No. 5, pp. 165-176, figs. 5).—

As a result of a study of the germination, as well as the foliar, flower, and fruit characters of various kumquats, together with the material in the principal herbaria of Europe and America, the author concludes that the kumquat should be placed in a new genus midway between Atalantia and Citrus. The new genus Fortunella together with the four species known at present are here described. The genus is subdivided into the subgenus Eufortunella and a new subgenus Protocitrus.

Windbreaks, hedges, and ornamentals for irrigated sandy soils of eastern Oregon, R. W. Allen (Oregon Sta. Bul. 125 (1915), pp. 3-21, figs. 12).—The author discusses in detail the care and development of windbreaks for crop protection as well as the use of shade trees, hedges, and other ornamental plants for farmyards. A limited number of native plants that deserve recommendation for ornamental use are briefly described. The subject matter is based upon the results of experiments with windbreaks and ornamental trees that have been conducted at the Umatilla Station during the past five years. The results of these tests are presented in tabular form.

Flower gardens.—A selected list of books (*New York; N. V. Pub. Libr.*, 1915, pp. 11).—A selected list of books, prepared by The New York Public Library, dealing with gardens and garden design; special kinds of gardens; individual plants, flowers, shrubs, and trees; gardens of various countries; the pleasures of a garden; children's and school gardens; and miscellaneous garden topics. Books on wild flowers are not included.

The care of house plants (Missouri Bot, Gard, Bul., 3 (1915), No. 2, pp. 25-31),—This paper points out the usual causes of failure in growing house plants, and indicates in a general way the plants and flowers best adapted for the home during the winter months.

Geraniums (Missouri Bot. Gard. Bul., 3 (1915). No. 2, pp. 31–33).—During the summer of 1914 the Missouri Botanical Garden made careful observations on 367 varieties of geraniums with reference to heat and drought resistance; profusion of flowers; color, shape, and size of flower clusters; character of foilage, etc. A list is given of 76 varieties for which favorable growth and satisfactory flower production have been recorded.

FORESTRY.

[Report of] forestry investigations, E. G. Cheyney (Minnesota Sta. Rpt. 1914, pp. 55-59).—This comprises a brief statement of progress made in various lines of work at the Cloquet Forest Experiment Station, silvicultural studies at Itasca Park, and prairie tree planting investigations at Morris.

Partial data are given in connection with a planting test conducted at the station. It was found that the cost of planting 1.000 trees in a gravelly situation with a wedge spade was \$2 as compared with a cost of \$4 per thousand where the holes were dug with a mattock. Ninety-one per cent of the spade-planted trees were alive in the fall as compared with 80 per cent of those planted with a mattock. In other situations, however, the wedge spade was not so satisfactory.

Among the exotic hardwoods and shrubs being tested several varieties of poplar and willow from China received from the Department of Agriculture are making good growth and give promise of surpassing the native species. Experiments to determine the success of seed trees for restocking cut-over areas show that only in very favorable situations will reproduction be quick and even then the price of the lumber left in the seed trees would go a long way toward paying the cost of planting the land uniformly.

A test of butternut and black walnut seedlings from Minnesota seed which is being made in Itasca Park shows that the butternut can withstand the winter successfully but that the black walnut is severely injured. Experiments in late seeding for the purpose of preventing "damping off" in coniferous stock have shown conclusively that during an average season white and Norway pine sown as late as July 12 have developed into sturdy seedlings capable of resisting the winter. The seedlings showed no trace of "damping off."

In connection with the prairie tree planting investigations the work done so far shows that reliable data with reference to the best species of trees for farm planting, methods of planting, cultivation, etc., can not be obtained from the study of the groves now in existence, their history being too incomplete.

Forest conditions of Mississippi (Miss. Geol. Survey Bul. 11 (1913), pp. 166, pls. 4, figs. 2).—This bulletin consists of reprints of Bulletins 5 and 7 of the same series (E. S. R., 23, p. 344; 24, p. 739), together with a statistical supplement by E. N. Lowe containing data on forest products of Mississippi based on the U. S. Census of 1910. A note on the flora of the forest regions of Mississippi by the same author has also been added.

Possibilities of municipal forestry in New York, N. C. Brown (N. V. State Col. Forestry, Syracuse Univ., Ser. XIV, No. 2 (d) (1914), pp. 19, figs. 8).—The author gives an account of the Syracuse Municipal Forest, calls attention to other similar activities in the State and to successful municipal forests in Europe, and points out the value of municipal forests from the scenic, sanitary, and economic points of view.

The height growth of trees, Bernbeck (Bot. Jahrb. [Engler], 59 (1914). No. 5, Beiblatl 114, pp. 19-24).—A brief discussion of the influence of soil, atmosphere, and light on the height growth of trees.

Growth studies in forest trees.—II. Pinus strobus. H. P. Brown (Bot. Gaz., 59 (1915), No. 3, pp. 197-24t, pls. 2, flgs. 2).—In continuation of a growth study of the pitch pine (P. rigida), previously noted (E. S. R., 28, p. 49) the results are given of a similar study of the white pine (P. strobus).

The important phases discussed include the microscopical characters of the xylem; winter condition of secondary cortex and cambium, awakening of secondary growth, rapidity and intensity of growth, irregularity and termination of secondary growth, and differentiation in the annual rings in aerial parts; primary growth in aerial and underground parts; and secondary growth in underground parts.

A bibliography of cited literature is appended.

Forest fires; their prevention and control, G. LUNDBERG (Skogsvårdsför. Tidskr., No. 2 (1915), pp. 113-156, figs. 26).—An account of various types of forest fires and methods of preventing and controlling them.

Forest valuation, H. H. Chapman (New York: John Wiley & Sons, 1915, pp. XVI+310).—A text-book and popular guide to that part of the subject of forest finance usually termed "forest valuation." Forest statics, the other part of forest finance, is discussed in a single chapter. The first four chapters of the work are devoted to a summary of economic subjects and tenets, such as values, outlay and income, interest, and valuation of assets. Chapter 5 deals with formulas of compound interest. The succeeding chapters discuss investments and costs in forest production, the valuation of forests, forest statics—the balance sheet—profits, the appraisal of damages, forest taxation, stumpage values, future value of forest products, risks, field appraisals of timber stumpage, and comparison of forest values with agricultural values.

The appendix contains summaries of formulas of compound interest and in forest valuation, definitions of symbols, and tables of compound interest and logarithms.

Forest products of Canada, 1913.—Lumber, lath, and shingles, R. G. Lewis, W. E. Dexter, and W. G. H. Boyce (Dept. Int. Canada, Forestry Branch But. 48 (1915), pp. 55, pl. 1).—This is the usual report (E. S. R., 30, p. 46) on the quantities, kinds, and values of lumber, lath, and shingles manufactured in the Dominion and in the various Provinces for the calendar year 1913. The total value for the year was \$70,644,362, of which lumber represents \$65,796,438.

Tests of wood preservatives, H. F. Weiss and C. H. Teesdale (U. S. Dept. Agr. Bul. 145 (1915), pp. 20, pls. 6, fig. 1).—This bulletin describes experiments conducted to determine the practical value as wood preservatives of some thirty compounds and chemicals. The experiments were performed by E. Bateman, C. J. Humphrey, Rath Fleming, and R. E. Prince. The preservatives tested include coal-tar creosotes of various fractions, water-gas-tar creosotes, wood tar and creosote, copperized oil, fuel oil, kerosene, zinc chlorid, zinc sulphate, sodium silicate, sodium fluorid, and other preparations of similar nature listed under trade names.

The methods of conducting the tests are described and the results are presented in a series of tables. The data given show the physical and chemical properties of the preservatives, penetrance of the preservatives and their effect on the strength of wood, permanence of the preservatives after injection into wood, inflammability of treated wood, toxicity of preservatives to Fomes annosus and F. pinicola, corrosive action of the preservatives, and discoloration of wood treated with preservatives and painted.

The experiment shows in general that highly viscous oils do not readily penetrate, while oils with low viscosities penetrate wood readily. To secure the best results, both the wood and the preservative should be sufficiently heated during the pressure period and the treatments should not be made too rapidly on account of the low thermal conductivity of wood. With water-soluble salts these precautions are not important. Judging from the toxic values secured in this work there is, in practice, being forced into wood about one and one-half times as much zinc chlorid and from ten to twenty times as much coal-tar creosote as is necessary to prevent decay. It is believed that more economic results, especially when decay is accompanied by mechanical deterioration, can be secured by diffusing the preservative more thoroughly through the wood than by saturating the outer fibers and attempting to retain in the wood the more toxic volatile constituents through admixtures of nonvolatile constituents. the case of zinc chlorid the factor of safety is very low. To secure the best results the injection of from 0.4 to 0.5 lb. per cubic foot now commonly used should be increased.

Wood treated with oils in every case ignited at lower temperatures than untreated wood. Prolonged seasoning of such wood, however, raises considerably its ignition temperature. It seems advisable to season such treated timber before placing it in positions subject to fire. Wood treated with water-soluble salts was in general less difficult to ignite than untreated wood, nevertheless the presence of such preservatives usually renders the wood slow burning and easily extinguishable.

The results of the tests made indicate that woods treated with zinc chlorid, sodium fluorid, and other water-soluble salts might be successfully painted. No definite conclusions can be drawn in regard to this point until the results of tests in cooperation with the National Paint Manufacturers' Association become available.

DISEASES OF PLANTS.

Annual report of the botanical experiment station at Proskau in 1913. R. EWERT (Ber. K. Lehranst. Obst u. Gartenbau Proskau, 1913, pp. 135-150, flgs. 3).—The author notes that young Fertility pear trees this year, as pre-

viously, set fruit in case of frost-killed pistils as well as of uninjured ones, and a considerable proportion of such fruit was still developing on August 15.

Cronartium ribicola, which is said to attack black currants mainly through the stomata of the lower leaf surface, was largely checked by an application of 1 per cent Bordeaux mixture to that surface (the case of Fusicladium on pear giving similar results from the same treatment), but the fruits were unfavorably affected in growth and appearance by this treatment. Red currants were amply protected against Pseudopeziza ribis by spraying the upper leaf surface. Comparative tests with California mixture employed against P. ribis on currants susceptible thereto resulted favorably.

The influence of air-horne chemical products escaping from factories and settling on vegetation was again studied. See page 826.

A table showing the degrees of attack by fruit disease on pears by $Fusi-ctadium\ pirinum\ and\ Mycosphwrella\ sentina\ in\ relation\ to\ the\ weather\ for\ 1904–1913\ is\ also\ given.$

Observations on diseases in nursery and orchard, O. Schindler (Ber. K. Lehranst, Obst. u. Gartenbau Proskau, 1913, pp. 33-38, fig. 1).—In addition to mention of some insect injuries, brief notes are given of plant diseases.

Spraying for American gooseberry mildew March 17 and April 4 with 0.5 per cent potassium sulphid or 20 per cent lime sulphur, and on May 3 and June 3 with 0.5 per cent potassium sulphid or 2 per cent lime sulphur gave very good results, which were in some degree impaired, however, by a blowing rain about June 3. Repetition of this treatment on June 24 showed no results. A strong (20 per cent) solution of lime sulphur considerably decreased injury to peach foliage from Exoascus deformans persiew.

Recent studies at the Agricultural Botanical Institute at Munich, L. Hiltner (Wiener Landw. Zty., 64 (1914), Nos. 76, pp. 713-715, figs. 3; 77, p. 7.20, figs. 5).—It is stated that Fusarium attack on rye in early spring was prevented by soaking the seed in 0.1 per cent corrosive sublimate, and that the same treatment seems to promise good results as regards germinability, vigor, and growth in case of legumes. It has been found that lupines showing poor development on limy soil may be restored to normal vigor by spraying several times with 0.5 to 0.75 per cent iron sulphate, but that the chlorosis reappeared after spraying with milk of lime.

A series of experiments indicated that spraying or brushing on 1 to 2 per cent solutions of potassium or magnesium salts in case of several economic plants gives increased growth and vigor.

The effects of fertilizers applied through the medium of the soil are briefly noted. Addition of humus (which acting alone was ineffective) to serradella and mustard which made poor growth in sand with otherwise liberal nutriment gave striking results, and a like effect followed the addition of certain pulverized rocks to mineral nutritive media.

Second contribution to the mycological flora of Tunis, R. Maire (Bul. Soc. Hist. Nat. Afrique Nord, No. 9 (1914), pp. 254-260, figs. 3).—About 40 species are listed, of which 2 are described as new, these being named, respectively, Protomyces helminthia on Helminthia echioides, and Lophidium chamæropis on Chamærops humitis.

New species of Colletotrichum and Phoma, P. J. O'GARA (Mycologia, 7 (1915), No. 1, pp. 38-41).—The author describes and names as new species C. destructivum parasitic on the leaves, petioles, and stems of clover, C. solanicolum in the subterranean stems of potato, and C. salmonicolor and P. rostrata on the leaves and stems of Asclepias speciosa, all in Salt Lake Valley, Utah.

The control of root knot, E. A. Bessey and L. P. Byars (U. S. Dept. Agr., Farmers' Bul. 648 (1915), pp. 19, figs. 20).—This is a popular bulletin in which

descriptions are given of the root knot of various plants due to Heterodera radicicola and suggestions for its control.

The means of control consist principally in the growth of resistant plants, lists of which are given. In orchards and ornamental gardens no very satisfactory methods of control have been determined. In greenhouses and seed beds steam fumigation is recommended, and for field purposes rotation of crops is the most practical method known.

The conidial form of Ophiobolus herpotrichus, E. Voges (Centbl. Bakt. [etc.], 2, Abl., 42 (1914), No. 1-4, pp. 49-64, figs. 9).—The author, referring to work previously noted (E. S. R., 29, p. 211; 31, p. 542), now states that an Acremonium (A. alternatum), and not a Fusarium, is found to be the conidial form of O. herpotrichus. Among the forms present in the fungal complex characterizing stalk disease of cereals. F. rubiginosum, Rendersonia herpotricha, Mucor racemosus, Leplospharia tritici, Cladosporium herbarum, Alternaria tenuis, Ascochyta sp., and Seploria sp. have been identified.

Control of stem rust of rye, 11. C. MÜLLER and E. Molz (Landw, Wehnschr, Sachsen, 16 (1914), No. 7, pp. 60, 61; abs. in Zischr, Landw, Versichsw, Österr., 17 (1914), No. 6-7, pp. 647, 648).—Experimentation showed that Urocystis occulta on rye is easily controlled by steeping the seed in 0.5 per cent copper sulphate for 16 hours, in 0.25 per cent commercial formaldehyde for 15 minutes, or in water at 20° °C, for 15 hours or at 30° °C, for 14 of hours. The two lastnamed (reatments were followed respectively by steeping in water at 50° °C, for 10 minutes or at 52° °C, for 5 to 40 minutes without very serious impairment of germinability.

Leaf spot of beans, O. Appel (Milt, Deut, Landw, Gesetl., 29 (1914), No. 18, pp. 249-251, figs. 3; abs. in Ztschr. Landw. Versuchsw. Österr., 17 (1914), No. 6-7, p. 648).—An unusually threatening recent increase of infection of beans by Glavsporium (Collectotrichum) lindemuthianum is noted. The remedies available are careful seed selection, destruction of all infected plants, employment of open ground for planting, and spraying with 0.5 per cent Bordeaux mixture once or twice before the blooms open.

Eggplant rots, F. A. Wolf (Mycol. Centbl., 4 (1914), No. 6, pp. 278-287, figs. 4).—A detailed account of a study already noted (E. S. R., 31, p. 344).

Further studies on the spread and control of hop mildew, F. M. Blodgett (New York State Sta. Bul. 395 (1915), pp. 29-80, pts. 2, figs. 2; abs. in Phytopathology, 4 (1914), No. 6, pp. 400, 401).—In continuation of studies of the hop mildew (E. S. R., 29, p. 346) the author gives the results of three years' experiments on control, together with further observations on the life history of the fungus, relation of the weather to the spread of the epidemic, etc.

The perithecia or winter fruit bodies of the fungus have been found to reach maturity in March and have been shown capable of causing infection in the greenhouse at that time of the year. Artificial inoculations in the field indicated that the period of incubation is about ten days.

In the experiments on the control of the disease, flowers of sulphur, heavy flour sulphur, and fine flour sulphur have been compared, and also the effect of lime used in conjunction with sulphur. Flowers of sulphur have been found variable in mechanical condition, and it was impossible to apply satisfactorily some forms. It was also determined that injury following the use of this form of sulphur was due to the presence of considerable amounts of sulphuric acid. Extremely fine flour sulphur also proved difficult to apply, and flour sulphur of a medium degree of fineness seemed to be most efficient, easiest to handle, and the cheapest of the fungicides tested. Sulphur and lime mixture proved less effective than sulphur alone.

Stem rot of sweet potato, L. L. Harter and Ethel C. Field (Ztsehr. Pflanzenkrank., 24 (1914), No. 4, pp. 204-207).—This is a brief account of investigations which have already been noted elsewhere (E. S. R., 32, p. 50).

Black rot, shed burn, and stem rot of tobacco, J. Johnson (Wisconsin Sta. Research But, 32 (1914), pp. 63-86, figs. 7).—The results are given of studies on some warehouse and curing house troubles of tobacco.

The black rot, due to Sterigmatocystis uigra, is said to cause considerable loss in the process of fermentation under certain conditions. The fungus requires in its development a moisture content of 26 per cent or more, a temperature of from 30 to 44° C. (86 to 111.2° F.), together with proper aeration.

In order to control this disease regulation of warehouse conditions so as to keep down the moisture content and provide proper temperature is recommended. Fundigation with formaldehyde may also be adopted where the disease has previously been very prevalent.

The author states that the difference between shed burn and stem rot, which are due to one or more fungi, among them a species of Fusarium, appears to be one of location rather than a difference in causal organisms. If the midrib is attacked, the resulting decay is called stem rot, while if the leaf tissue is decayed it is called shed burn.

These diseases may be controlled by regulation of temperature and humidity in the curing shed in connection with proper ventilation.

The yellow blight of the tomato, D. C. George (Washington Sta. Popular Bul. 82 (1915), pp. 4).—This is a popular bulletin based largely upon a previous publication of the station (E. S. R., 32, p. 444).

Fire blight, I. D. Cardiff (Washington Sta. Popular Bul. 80 (1915), poster).— This publication is intended to call attention to the prevalence of the fire blight of pears, apples, etc., and gives brief suggestions for control.

Life history of a new species of Sphærella, B. B. Higgins (Mycol. Centbl., 4 (1914), No. 4, pp. 187-193, figs. 2).—A fungus, said to be new and to cause a disease of Prunus pennsylvanica, is described under the name Mycosphærella nigerristigma. The name 8. nigerristigma is, however, preferred.

Roncet of grape, J. Bernatsky (Ztschr. Pflanzenkrank., 24 (1914), No. 3, pp. 129-139, figs. 2).—The author, discussing this phenomenon and allied abnormalities describes the internal appearance of the deformed regions in cases studied, and suggests possible causes, which it is said may differ considerably as to character and mode of action.

[Two fungus parasites of conifers in Scotland], W. Somerville (Quart. Jour. Forestry, 9 (1915), No. 1, pp. 68, 69, pl. 1).—Chrysomyxa abietis and C. rhododendri are said to have been noted one or more times previously on conifers at points in Scotland, and a watch for these fungi is recommended.

Withertip of fir in Sweden, T. Lagerberg (Meddel. Stat. Skogsförsöksanst. (Mitt. Forstl. Vers. Anst. Schwedens), No. 10 (1913), pp. 9-44, I-IV. figs. 19).—This is substantially the same as a report already noted from another source (E. S. R., 30, p. 453).

On the mode of infection of larch canker and the possible means of preventing it, W. E. HILEY (Quart. Jour. Forestry, 9 (1915), No. 1, pp. 7-17, pls. 3).—Among the ways in which Dasyseypha (Peziza) calyeina may infect larch are mentioned wounds made by frost, hail, the larch aphis (Chermes abietis), or abrasions due to movements of men, animals, or air, though the dangers from such sources has, it is thought, been overestimated.

Owing to the death of young branches the cankers of most direct importance to foresters are those induced after the first two or three years of growth.

Examinations of anatomical and physiological data are not declsive as to whether the mycelium passes from a dead branch to the main axis through the wood or just outside it. Death of dormant buds is considered as a possible means of infection of the stems, but probably this is of no great importance. It is held that the most important source of infection are the dead limbs left on the stems, this suggesting removal of affected branches before they are dead, preferably during dry months when spores of this fungus are not being given off.

A disease of pine shoots (Quart, Jour, Forestry, 9 (1915), No. 1, pp. 64, 65).—
A fungus, said to be more common on the Corsican pine than on Scotch pine and some other conifers, has been identified as Cenangium abictis. Infection occurs in late autumn or winter. The leaves begin to fall rapidly in early summer, the shoots of the previous year's growth often being completely defoliated. The bud of an infected shoot rarely expands at all. Both ascospores and one to three celled conidia in large quantities are said to be produced by the fungus.

A leaf cast of pines in Sweden, T. LAGERBERG (Meddel, Stat. Skogsförsöksanst. (Mitt. Forstl. Vers. Anst. Schwedens), No. 10 (1913), pp. 139-180, XVII-XXII, figs. 8).—A leaf disease of pines is described in its several stages and as to its effects on the foliage and trees. It is sald to show pycnidia corresponding to those borne by Leptostroma pinastri, the conidial stage (Lophodermium pinastri) being already known. A bibliography is given.

A disease of oaks in Westphalia, Hey (Ztschr. Forst u. Jagdw., 46 (1914). No. 10, pp. 595-598).—The author cites facts recently observed by himself which are held to indicate that Armillaria mellea is the cause of the dying out of oak trees and also of beech in one case noted.

A timber rot accompanying Hymenochæte rubiginosa, H. P. Brown (Mycologia, 7 (1915), No. 1, pp. 1–20, pls. 3).—The author describes the results of invasion by H. rubiginosa and its saprophytic activity in case of decorticated chestnut (also, but more rarely, of oak) near Ithaca, N. Y., and also the development and habits of this fungus.

The fruit bodies are annual and xerophytic, spores being shed intermittently during moist periods for several months. A superficial peripheral type of decay usually accompanies the typical decay due to this fungus.

Studies in dry rot, V, C. Wehmer (Mycol. Centbl., 4 (1914), Nos. 5, pp. 241–252, fig. 1; 6, pp. 287–299, pls. 2).—In continuance of previous reports (E. S. R., 31, p. 248) the author gives detailed results of studies on conditions as favorable or unfavorable to development on structural woods, etc., by Merulius, including the influence of previous sterilization, of impregnation with nutritive substances, and of lowering the temperature during the tests.

Air-dry or dampened, but not strictly sterile, fir wood was not severely attacked by detached mycelium of Merulius, even in a moist chamber, the experiments indicating a high degree of sensitiveness of this fungus to conditions as regards both nutritive materials and the presence of other organisms (bacteria, yeasts, and other fungi). Other experiments with strictly sterile moist heartwood or sapwood gave a growth the luxuriance of which was in close relation with the degree of moisture present in the materials attacked (moisture of the air showing little if any influence). Spore development was not obtained on either air-dry or dampened wood. Attached mycelium, however, proved much less sensitive to conditions hindering growth in detached portions.

The liability to extension by Merulius appears, therefore, to be in practice somewhat limited by the tendencies above noted.

ECONOMIC ZOOLOGY-ENTOMOLOGY.

Handbook of medical entomology, W. A. Riley and O. A. Johannsen (Ithaca, N. V.: The Comstock Publishing Co., 1915, pp. 1X+348, pl. 1, figs. 174).—The object of this work, as stated by the authors, "is to efford a general survey of the field, and primarily to put the student of medicine and entomology in touch with the discoveries and theories which underlie some of the most important modern work in preventive medicine."

In an introduction the authors discuss early suggestions regarding the transmission of disease by insects and the ways in which arthropods may affect the health of man. The subject is then taken up under the headings of arthropods which are directly poisonous; parasitic arthropods affecting man; accidental or facultative parasites; arthropods as simple carriers of disease germs, as direct inoculators of disease germs, as essential hosts of pathogenic organisms, and as essential hosts of pathogenic protozoa; some possible but imperfectly known cases of arthropod transmission of disease, and keys to the arthropods noxious to man. In an appendix the use of hydrocyanic acid gas against household insects with the details relating to household funigation and lesions produced by the bite of the black fly are dealt with.

A 14-page bibliography and a complete subject index are included.

Entomology, or the study of insects, and its importance, E. S. Tucker (Louisiana Stas, Crop Pest Notice 3 (1915), pp. 3-8).—This is a popular introduction to the subject. The author points out the importance of a knowledge of insects in order that the detrimental and beneficial ones may be distinguished and that control measures may be intelligently applied.

Habits and instincts of insects up to the growth of the social instincts, O. M. Reuter (Lebensgewohnheiten und Instinkte der Insekten bis zum Erwachen der sozialen Instinkte. Berlin: R. Friedländer and Sohn, 1913, pp. XVI+448, figs. 84).—This work is separated into 26 chapters in which the author deals at length with the bionomies of insects.

Cyanid of potassium in trees (Agr. News [Barbados], 14 (1915), No. 332, p. 26).—The accounts previously noted (E. S. R., 32, pp. 152, 754) having come to attention several tests were made by the Imperial Department of Agriculture to determine what effect cyanid has on certain plants. Three trees were used, namely, a small mulberry (Morus alba), king of flowers (Lagerstræmia indica), and a red gum (Bursera gummifera), the cyanid being applied in a hole \frac{3}{2} in, in diameter, bored into the trees to a depth of about 1\frac{1}{2} to 1\frac{3}{4} in. The holes were then filled with finely crushed cyanid of potassium and plugged with paraffin wax on October 21, 1914.

In each case the trunk of the tree was considerably injured and the method is considered liable to result in serious injury to the plants.

[Report of] department of entomology (Oregon Sta. Rpt. 1913-1914, pp. 13-17).—The common eastern lady beetle (Megilla maculata) has been introduced from the East and is being reared in confinement.

The results of insecticide investigations have been summarized in part as follows: "Lime-sulphur plus arsenite of zinc. lime-sulphur plus arsenate of lead (acid), and lime-sulphur plus arsenate of lead (nonacid), in all strengths caused serious burning. If anything, the nonacid injury was slightly the worst. Lime-sulphur caused considerable injury, but not one-half as much as in the combination sprays. Arsenite of zinc alone and in all strengths caused considerable burning. The burning was different, however, from that of the combination and lime-sulphur sprayed trees. With the combination sprays the entire leaf was destroyed or else the injury covered a distinct portion, all parts of which were discolored. Scab spots on the leaves appeared black, ordinary

leaf tissue brown. . . . Arsenate of lead (acid) and arsenate of lead (non-acid) did not cause injury in any case when used alone. In experiments with arsenite of zinc, etc., where injury did occur, the injury did not begin to show up badly for about 5 days, when suddenly, overnight, it appeared at its worst. The check trees, sprayed with water, did not show injury. . . .

"Arsenite of zine is a quicker-acting poison than arsenate of lead, acid or nonacid, and remains in suspension much better. Acid arsenate of lead is a quicker-acting poison than the nonacid and remains in suspension better. Nonacid arsenate of lead is slow in its action, but is satisfactory in that death finally occurs. Lime-sulphur in the experiments conducted has not proved to have much value as a stomach poison. Lime-sulphur with arsenicals seems to retard to a more or less extent the action of the poison, and it is possible for larvae to feed on foliage sprayed with weak strengths of lime-sulphur plus arsenate of lead and recover, if transferred to fresh foliage within a few days. . . Lime-sulphur probably acts as a repellent to biting insects in the same way that Bordeaux does against the potato flea-beetles."

The larvæ of tent caterpillars (Malacosoma crosa and M. pluvialis) were used in the experiments.

Report on injurious insects in Finland, 1911 and 1912, E. REUTER (Landtbr. Styr. Meddel. [Finland], Nos. 87 (1914), pp. 18; 93 (1914), pp. 14).—These annual reports of the entomologist of Finland discuss the occurrence of the more important insect enemies of crops during the years 1911 and 1912.

Report of the imperial pathological entomologist, F. M. Howlett (Rpt. Agr. Research Insl. and Col. Pusa, 1912-13, pp. 78-83).—A brief report of the work of the year with ecto-parasites, fruit flies, etc.

[Annual report of the government entomologist of Uganda], C. C. Gowdey (Ann. Rpt. Dept. Agr. Uganda, 1914, pp. 36-58).—The author here reports on the more important insect enemies of the principal crops of Uganda, particularly of coffee and cotton. The yellow-headed coffee borer (Dirphya [Nitocris] princeps) and the coffee-berry borer (Stephanoderus coffee) which attack coffee, and the spiny bollworm (Earias insulana). Oxycarcus hyalinipennis, and the leaf-footed plant bug (Leptoglossus membranaceus), which attack cotton, are given particular consideration.

Proceedings of the German Association of Economic Entomology, edited by K. Escherich and F. Schwangart (Zlschr. Angew. Ent., 1 (1914), No. 1, pp. 240, pls. 3, jigs. 61).—The papers presented at the first annual meeting, held at Würzburg, October 21 to 24, 1913, include the following: The Aims and Problems of the German Society of Economic Entomology, by K. Escherich (pp. 14-19); The Fight Against the Grapevine Phylloxera in Prussia, by E. H. Riibsaamen (pp. 20-49); The Vine Phylloxera in Franconia, by Orth (pp. 50-58); Experimental Demonstration of a Biological Race Difference in the Phylloxera from Lorraine and from Southern France, Peritymbia (Phylloxera) vitifolii perrastatrix, by C. Börner (pp. 59-67); Economic Entomology in Italy, by R. Heymons (pp. 68-83); Economic Entomology in Germany, by L. Reh (pp. 84-94); Economic Entomology in the German Colonies, by G. Aulmann (pp. 95-136); The Royal Institution for Bee Keeping, Investigations at Erlangen, by E. Zander (pp. 137-146); The Biology of the Tsetse Flies, by E. Teichmann (pp. 147-159); A New Grain Pest in Hungary (Halmeule: Tapinostola musculosa), by J. Jablonowski (pp. 160-171); The Habits of Dipterous Parasites of Caterpillars (Raupenfliegen), by H. Prell (pp. 172-195); The Mulberry or West Indian Peach Scale and Its Control by Parasites, by J. Bolle (pp. 196-213); Economic Entomology and Bird Protection, by K. Haenel (pp. 214-222); and The African Silkworms and Their Agricultural Importance, by A. Schultze (pp. 223-231). A list of the members is appended.

Insect enemies of the beet root in the south of France, F. Picard (Vie Agr. et Rurate, 3 (1914), No. 14, pp. 390, 391).—A brief discussion of the more important beet pests.

Insect enemies of locusts and of noxious acridians in Russia.—I, Coleopterous enemies, I. A. Portchinsky (Trudy Būuro Ent. [8t. Petersb.], 11 (1914), No. 1, pp. 68, pls. 2, figs. 22; abs. in Rev. Appl. Ent., 2 (1914), Ser. A. No. 7, pp. 473–475).—In this paper the author deals at length with the beetles which destroy the eggs of Orthoptera, 16 belonging to the genus Mylabris and 3 to the genus Epicauta.

The pea thrips, GAUMONT and VUILLET (Bul. Soc. Nat. Agr. France, 74 (1914), No. 2, pp. 168-173).—This article relates to Frankliniella robusta (Thrips pisivora) which is a source of considerable injury to peas in France.

In 1913 this thrips was abundant on peas, beans, and sweet peas in the Aisne. It is said to occur in abundance in the blossoms of trefeil at Bourg-la-Reine, Department of Seine, in May, and individuals have been found in the blooms of crown vetch and lucern at Beaune, Ajuga reptans at Chaumont-en-Vexin, and Echallium claterium at Marseille. Thus it appears that this thrips is very widely distributed in France and that it can survive at least temporarily on other plants than peas and beaus.

Maine aphids of the rose family, EDITH M. PATCH (Maine Sta. Bul. 233 (1914), pp. 253-280, pls. 3, figs. 6).—This paper gives brief descriptive accounts and drawings of those aphids found in Maine upon members of the rose family (Rosacea). The most serious of the apple aphids has been previously noted (E. S. R., 30, p. 548), but the plum aphids have not previously been worked up.

The species considered are the woolly aphid of hawthorn leaf, Prociphilus corrugatans on Juneberry (Amelanchier) and Crategus; Schizoneura lanigera, Macrosiphum cratagi, Aphis avena, A. brevis, and A. bakeri on Crategus; Myzus porosus on strawberry; Myzus cerasi, A. furcala n. sp., Myzus persica, A. cerasifolia, and A. tuberculata n. sp. on cherry; A. cerasifolia, A. prunorum, A. cardui, Phorodon humuli, and Hyatopterus arundinis on plum; S. lanigera on mountain ash; S. lanigera, A. avena, A. pomi, A. sorbi, and M. persica on apple; A. brevis on Pyrus japonica; Macrosiphum rosa, M. solanifolii, M. dirhodum, and Myzus rosarum on roses; A. rubiphila n. sp., and Macrosiphum rubicola on raspberry; and A. spiracola n. n., A. spiraphila n. sp., and Macrosiphum spiracola n. sp., on Spiræa.

Brief notes on aphid control and a list of the literature cited are included. The woolly apple aphis, A. C. Baker (U. S. Dept. Agr. Rpt. 101 (1915), pp.

The woolly apple aphis, A. C. Baker (U. S. Dept. Agr. Rpt. 101 (1915), pp. 55, pls. 15, figs. 3).—This is a report of studies of Eriosoma (Schizoneura) lanigera commenced in the spring of 1912.

In experiments conducted it was found that the species does not migrate to Ribes as is the case with *E. ulmi* in Europe. The results of the author's experiments did not agree with those of Dr. Patch (E. S. R., 28, p. 251), who reports transferring from elm to apple the species which she considered as *E. americana*, in that the species which he considered *americana* would not feed upon apple; they did agree, however, in that the elm was proved to be the winter host of *E. lanigera*, so that he credits her with having first discovered that the woolly aphis migrates from the elm to the apple in the spring and in the fall returns to the elm. The negative results obtained from experiments with Ribes indicate that three species develop on elms, namely, *E. ulmi*, *americana*, and *lanigera*.

The subject is taken up under the headings of early history; name, including synonymy; methods of study; forms of the species, including technical descriptions; and a detailed study of the structure, habits, etc., of the species, including molts, digestive system, injuries, body fluids, muscles, movement,

migrations, reproduction, wax secretion, respiration, and nervous system. Under reproduction the author treats of the reproductive system, parturitlen, number of young, and courtship.

The life history of this species is summarized as follows: "The egg is laid, as a rule, upon the bark of elm in crevices, though occasionally it is laid upon other trees. In the spring, toward the first of April, it hatches, and the young stem mother so produced migrates to the base of a bud. Here she may remain for some days before the bud opens. Upon opening, the leaves curl or 'rosette' about the insect, and in this house she produces her young. This second generation is wingless and lives within the curled leaves or upon the tender twigs. The generation matures late in April or in early May. It in turn produces a third generation, which is present upon the elm leaves from about May 1 until early June. An insect of this third generation is winged and is known as the spring migrant. It flies from the elm leaves to apple or related plants, settling upon the leaves, twigs, and water sprouts. Here it produces the fourth generation, which is wingless and which is the first generation on apple of the well-known woolly aphis, About July 1 this generation is mature and is giving birth to another generation, the fifth, which is exactly like it. Many individuals of this fifth generation migrate to the roots, but others remain upon the twigs. Those which remain above ground produce a generation of winged forms, the sixth generation, which is mature about the middle of September. These fall migrants may be found upon the trees until late autumn, but they nearly all migrate to the elms. Here they settle upon the bark and produce the sexual forms, males and females, small wingless, beakless individuals. These mate, and the female, known as the oviparous female, then deposits her solitary egg in a crevice of the bark, where it passes the winter to hatch as a stem mother the following spring,"

A list of the literature referred to in the text is appended.

The host plants and habits of Aphis rumicis, with some observations on the migration of, and infestation of, plants by aphides, J. Davidson (Ann. Appl. Biol., 1 (1914), No. 2, pp. 118-141, fig. 1).—The author reports upon investigations of the habits of aphidids, made during the year, which failed to furnish sufficient data upon which to base any definite conclusions, although many of the observations have suggested certain lines of inquiry. In the latter part of the paper he briefly discusses some of the factors which may underlie the questions of the migration of aphidids and the infestation of plants by them.

Preliminary notes on damage to apples by capsid bugs, J. C. F. FRYER (Ann. Appl. Biol., 1 (1914), No. 2, pp. 107-112, pls. 2).—This is a brief review of the literature on the subject and a report of observations made in English orehards. The distribution of the capsid attack in England is very local and is not known to be widespread in any district; at present it is known to occur sporadically in Kent, Suffolk, Nottingham, Worcester, and Hereford. The injured fruit is said to be almost unsalable and orchards were visited where from 30 to 50 per cent of the crop was affected, no account being taken in this estimate of fruit so damaged that it fell off before reaching maturity. Investigations of Lygus pratensis, Psallus ambiguus, Atractotomus mali, Plesiocoris rugicollis, and Orthotylus marginalis show.

An experiment was conducted by an orchardist which consisted in excluding the larvæ of these two species from a number of trusses and in inclosing them with others. The results show that the trusses from which the two species were excluded developed sound fruit, while the apples inclosed with them sustained typical capsid damage.

"The only treatment that can be suggested is a spray of soft soap and nicotin, or possibly soft soap and quassia, but success will depend on a nice estimation of the exact time to apply the wash, and the thoroughness with which the application is made."

The life history and habits of the pear thrips in California, S. W. Foster and P. R. Jones (U. S. Dept. Agr. Bul. 173 (1915), pp. 52, pls. 5, figs. 14).—
This is a detailed account of (Euthrips) Taniothrips pyri, based in part on studies previously noted (E. S. R., 24, p. 455). The subject is dealt with under the headings of the history, economic importance, character of injury, description, systematic position, anatomy, life history and habits, and natural enemies.

The San José scale and its control, A. L. QUAINTANCE (U. S. Dept. Agr., Furmers' Bul. 650 (1915), pp. 27, figs. 17).—This is a revision of Circular 124 of the Bureau of Entomology, previously noted (E. S. R., 23, p. 661).

The San José scale insect (Aspidiotus perniciosus), A. L. Melander (Washington Sta. Popular Bul. 78 (1915), pp. 7, figs. 3).—A popular account.

Monograph of the bombycine moths of North America, including their transformations and origin of the larval markings and armature, II and III, A. S. PACKARD (Mem. Nat. Acad. Sci., 9 (1905), pp. 272. pls. 61, figs. 19; 12 (1914), pl. 1, pp. IX+516, pls. 113, figs. 34).—Part 2 of this work (E. S. R., 8, p. 147) deals with the subfamily Ceratocampine. Before taking up the classification and life histories of the subfamily, which form the major part of the work, the author discusses such phases as coloration and protective attitudes of the Notodontide, the larval armature of the Ceratocampine, the caudal horn of the Ceratocampide, protective armature both in shape and color and defensive movements, coloration in the larva, dichromatism or color variation in the larva, the life history of Ceratomia amyntor, phylogeny of this subfamily, phylogeny of the Sphingide, origin of the Syssphingina and also the Symbombycina from the Notodontide, geographical distribution of the subfamily, etc. Twenty-three plates in color illustrate the larval and adult stages of the species.

The third part of the work deals with the families Ceratocampidæ (exclusive of the Ceratocampinæ), Saturnidæ (including hybrids), Hemileucidæ, and Brahmæidæ. A list of parasites of the species of these families is included. This third part, largely in manuscript form at the time of the author's death, has been edited by T. D. A. Cockerell. Thirty-four colored plates illustrate the larval stages of the species considered.

A new phycitid injurious to pine, II. G. DYAR (Inscutor Inscitia Menstruus, 2 (1914), No. 7, p. 112).—Pinipestis crythropasa, reared from cones of Pinus chihuahuana in the Chiricahua National Forest, Arizona, is described as new to science.

The caterpillars attacking the oaks of Richmond Park, with an account of an experimental spraying with lead chromate, R. H. Deakin (Ann. Appl. Biol., 1 (1914), No. 1, pp. 77-84, pls. 6).—This paper gives a detailed account of the work previously noted from another source (E. S. R., 31, p. 60).

The two commonest caterpillars were a leaf roller, *Tortrix vividana*, and the winter moth (*Cheimatobia brumata*). The spray used was made from a paste of the following composition: Lead chromate 50 per cent, soft soap 25 per cent, gelatin 1.5 per cent, and water 23.5 per cent. One lb. of the paste was used to about 30 gal. of water, thus giving 1 lb. of lead chromate to every 60 gal. of spray. Caterpillars fed on sprayed foliage either died at once or became starved and finally perished, so that no doubt remains as to the efficacy of the poison.

Control of the gipsy moth, W. C. O'KANE (N. H. Dept. Agr., State Moth Work Circ. 5 (1915), pp. 4).—A popular account.

On the causes and symptoms of flacherie and polyhedral disease of caterpillars, E. Fischer (Biol. Centbl., 34 (1914), Nos. 5, pp. 308–328; 6, pp. 357–371; abs. in Rev. Appl. Ent., 2 (1914), Ser. A. No. 8, p. 528).—The author has made investigations of the cause and symptoms of flacherie with caterpillars of three species of the genus Vanessa and with Pyrameis cardni, comparing his results with those obtained by Verson (E. S. R., 19, p. 256) with the silkworm in Italy. Flacherie and polyhedral disease are considered to be distinct on the basis of the form of the polyhedral bodies. The symptoms of both are discussed.

Biological notes on the larva of Tipula oleracea and its ravages in the vicinity of Avesnois in the spring of 1914, P. Désoil (Compt. Rend. Soc. Biol. [Paris], 77 (1914), No. 21, pp. 126, 127; abs. in Rev. Appl. Ent., 2 (1914), Ser. A. No. 10, pp. 606, 607).—This dipteran attacks chiefly grasses and clovers. Its injury commences toward the end of winter and the spring growth limits its spread, the larvae being active from October to May. The only practical measure of control consists in deeply plowing under the infested turf and in sowing in the months of March and April.

Ceratopogoninæ sucking the blood of other insects, F. Knab (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 3, pp. 139-141).—This article supplements that previously noted (E. S. R., 31, p. 455).

A new tachinid parasite of Diapheromera femorata, W. R. Walton (Proc. Ent. Soc. Wash., 16 (1914), No. 3, pp. 129-132, figs. 6).—It is stated that two tachinids have previously been known to be parasitic upon Phasmida. A third parasite reared at Milwaukee, Wis., from the common walking stick (D. femorata) is described as Euhallidaya screvinii n. g. and n. sp.

Lucilia sericata attacking a live calf, H. F. Hubson (Canad. Ent., 46 (1914), No. 12, pp. 416).—The author records observations at Strathroy, Ontario, in which a Holstein calf from 5 to 6 weeks old was attacked by the larva of L. sericala. The maggots were most abundant around the anns and base of the tail, where some had eaten into the flesh to a depth of about a quarter of an inch.

Descriptions of two new species of Strepsiptera parasitic on sugar cane insects, W. D. Pierce (Proc. Ent. Soc. Wash., 16 (1914), No. 3, pp. 126-129).—Stenocranophilus quadratus, a parasite of the destructive Stenocranus saccharirorus at Rio Piedras, P. R., and Pyrilloxenos compactus, a parasite of the sugar cane fly of India, Pyrilla sp., at Pusa, India, represent new genera and species.

Turnip flea-beetles.—Effect of turpentine and paraffin on the germination of turnip seed, G. II. Corbett (Ann. Sci. Bul. Roy. Agr. Col. Circucester, No. 4-5 (1914), pp. 84-88).—Experiments in which turnip seed was soaked from one to twenty days in turpentine or paraffin indicate that these substances do not retard germination when put under soil conditions but appear to hasten it.

Alfalfa attacked by the clover-root curculio, F. M. Webster (U. S. Dept. Agr., Farmers' Bul. 649 (1915), pp. 8, figs. 6).—This is a summarized account of Sitones hispidulus, an investigation of which reported by Wildermuth has been previously noted (E. S. R., 22, p. 758).

Its feeding habits so far as determined are almost exactly the same upon alfalfa as upon clover. Its attack on alfalfa, which has largely come to attention since the paper above mentioned was prepared, has occurred throughout all parts of Baltimore County, Md., at West Chester. Pa., about Salt Lake City, Utah, etc. Investigations of remedial and preventive measures have not as yet been carried out. Since the larvæ do not as a rule descend much more than 1 in. below the surface it is thought that disking or harrowing the fields as soon as the first hay crop is removed will break up the pupal cells and vast numbers of this pest be thus destroyed.

The cotton-boll weevil in Cuba, G. N. Wolcott (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 3, pp. 120-122).—Observations made in Cuba during the winter of 1911-12 and again during January and February, 1914, show that but little injury was done by the boll weevil. No boll weevils were found on cotton at Kingston, Jamaica. in March, 1914.

A braconid parasite on the pine weevil, Hylobius abietis, J. W. Munro (Ann. Appl. Biol., I (1914), No. 2, pp. 170–176, figs. 4).—A report of observations made on pine weevils and parasites collected in a plantation near Aberdeen.

This weevil is a source of injury in the adult stage only, doing considerable damage by gnawing the tender bark of young conifers and thus causing them to wilt and die. In the absence of conifers, it will readily attack birch, mountain ash, and oak. The author's observations indicate that *Brocon hylobii* may prove of considerable value in combating the weevil, which every year is becoming more and more common in newly formed plantations, especially in Scotland.

A revision of the North American species of the braconid genus Habrobracon, R. A. Cushman (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 3, pp. 99-108).—Seven species are recognized of which *Habrobracon variabilis*, reared from *Canarsia hammondi*, at Siloam Springs, Ark., and *H. platynota* from *Platynota* sp., at Hollywood, Cal., are described as new to science.

Descriptions of new chalcid flies, A. A. Girault (*Proc. Ent. Soc. Wash.*, 16 (1914), No. 3, pp. 169-119).—Among the parasites here described as new is Anaphoidea luna, a species obtained in shipments of the alfalfa weevil (*Phytonomus posticus*) from Italy.

Some notes on Xyleborus fornicatus (shot-hole borer), A. RUTHERFORD (Trop. Agr. [Ceylon], 42 (1914), Nos. 2, pp. 132-139; 3, pp. 220-222).—The burying of prunings from tea plants is said to have been the prevailing method applied in the control of X. fornicatus. Upon looking into the subject the author was able to find but a single experiment relating to their destruction in this way and was led to conduct the several tests here reported upon.

Nine in, of fine earth was not a formidable barrier to the emergence of the beetles. Slaked lime failed to kill even the larvæ after an exposure to it for 23 days. It was found that under laboratory conditions the beetles will continue to breed in prunings that are far gone in decay, provided these are not too dry, and even in the presence of slaked lime or quicklime, and that they are able to work their way up through as much as 7.5 in, of fine earth. Not only the adults but even pupe may remain alive in prunings left on the surface of the ground for as many as 13 days.

"In the light of our present knowledge the only means of control that can be recommended are, from an entomological point of view, (1) burning of prunings; (2) discovery of and elimination of, as far as practicable, breeding grounds in plants other than tea: (3) cultivation and manuring; and (4) prevention, so far as possible, of the infestation of fresh areas."

Descriptions of two parasitic Hymenoptera, S. A. Rohwer (Proc. Ent. Soc. Wash., 16 (1914). No. 3. pp. 141, 142).—Sympherta mnemonica, a primary parasite on Mnemonica auricyanca on chestnut and oak at Falls Church, Va.; and Podogaster eretrirorus, a parasite of Eretria sp., on Pinus ponderosa at Fort Bayard, N. Mex., are described as new.

Third annual report of the state bee inspector to the governor of the State of Iowa for the year 1914, F. C. Pellett (Ann. Rpt. State Bee Insp. Iowa, 3 (1914), pp. 126. pl. 1, figs. 63).—This report of the work of the year includes the proceedings of the meeting of the Iowa Bee Keepers' Association, held at Ames, November 17–19, 1914, and the papers presented, namely. Short History of Bee Keeping, by C. P. Dadant (pp. 32–37); Temperature and Humidity in the Wintering of Bees, by E. F. Phillips (pp. 37–56); Wintering

Bees in Iowa, by W. S. Pangburn (pp. 56-60); Fifty Years of Bee Keeping in Iowa, by E. Kretchmer (pp. 60-62); Individual and Cooperative Methods of Marketing Honey, by W. Foster (pp. 62-67); Experience with European Foul Brood, by J. I. Wiltsie (pp. 67-70) and by L. W. Elmore (pp. 70, 71); Experience with American Foul Brood, by D. E. Lhommedieu (pp. 71, 72); Discussion of Experiences with American Foul Brood, by J. W. Stine (pp. 73, 74); Trip Through Quebec, by C. P. Dadant (pp. 74-76); Honey Plants of Iowa, by L. H. Panmel (pp. 76-88); The Value of Bees in Horticulture, B. N. Gates (pp. 89-93); Bees as a Nuisance, J. D. Gustin (pp. 94-98); Basswood Planting, by G. B. MacDonald (pp. 98, 99); The Wild Bees of Iowa, by L. A. Kenoyer (pp. 99-110); and A New Method of Using Split Sections, by L. D. Leonard (pp. 111, 112).

Rocky Mountain spotted fever, L. D. Fricks (Pub. Health Rpts. [U. 8.], 30 (1915), No. 3, pp. 148-165, figs. 3; abs. in Jour. Amer. Med. Assoc., 64 (1915), No. 5, pp. 439, 440).—This report deals in large part with the work of eradicating the Rocky Mountain spotted fever tick, Dermacentor renustus (andersoni), during 1914.

Experiments to test the destruction of ticks by two bands of sheep numbering about 1,500 were made in the Bitter Root Valley, Montana, beginning about the middle of April and terminating about the middle of July, when the sheep were sheared, dipped, and returned to their owners. During the experiments sheep of both bands were searched frequently for dead and live ticks, and from the findings it was estimated that over 25,000 adult ticks were destroyed by the 1,500 sheep during the season. It is believed that this experiment shows conclusively that a high percentage of the total adult tick infestation can be destroyed by sheep grazing in one season.

Mites of the genus Tarsonemus causing disease on Gramineæ, G. H. Corbett (Ann. Sci. Bul. Roy. Agr. Col. Circnecster, No. 4-5 (1914), pp. 93-95, figs. 2).—In this brief review attention is called especially to a disease of oats caused by Tarsonemus spirifex.

A revision of the cestode family Proteocephalidæ, G. R. La Rue (III. Biol. Monographs, 1 (1914). No. 1–2, pp. 350, pls. 16),—The first part of this work contains historical data, including synonymy and definitions of the genera considered; a description of the technique employed; the anatomy and histology of the Proteocephalidæ, including characters of dlagnostic value; and a key to the better-known genera and species of the family. Descriptions of proteocephalid species follow, tegether with a comparative table of selected characters of Proteocephalus species; descriptions of proteocephalid species from Amphibia and Reptilia; comparative tables of selected characters of species of Ophiotænia and Crepidobothrium; and descriptions of species of Monticellia. This is followed by a discussion of the distribution, life history, and origin of the Proteocephalidæ.

The author concludes that the data presented by various workers show the life history of the proteocephalids to be essentially as follows: "The eggs and some of the ripe proglottids bearing eggs are voided by the host into the water, where they are eaten by an invertebrate, perhaps a worm, an insect larva, or a crustacean, or possibly the eater is a vertebrate, fish, snake, or an amphibian of the same species as the host or different. If the invertebrate or vertebrate furnishes a suitable habitat for the development of the parasite, the six-hooked embryo establishes itself and from it develops a plerocercoid about which the host produces a cyst. If the intermediate host be eaten by a vertebrate which furnishes—proper habitat for the adult parasite, the plerocercoid when it is released by the action of the digestive juices from its intermediate host and

from its cyst passes to the intestine and develops into the adult tapeworm. If the final host engulfs material containing eggs of the cestode harbored by itself or its congeners or perhaps by members of other species, the host becomes infected with the plerocercoids, and so it may function as a secondary as well as a primary host for its parasitic species. Cannibalism may be a means in the spread of the parasites harbored. The problems connected with the life history of these parasites must ultimately be settled by experimental methods."

A bibliography of nine pages is appended.

FOODS-HUMAN NUTRITION.

Lectures on food chemistry, compiled by W. Kerr (Nahrungsmittelehemie in Vorträgen. Leipsic: Akademische Verlagsgesellschaft, 1914, pp. XXXII+579, figs. 26).—This book consists of a compilation of lectures by different authors on various subjects of chemistry of foods and nutrition. Among the topics included are food legislation in the German Empire; the modern physicochemical basis of food chemistry; recent contributions to the chemical study of cell metabolism; the biology of milk; and a number of questions concerning the analysis and investigation of a number of different food materials.

A study of foods, Ruth A. Wardall and Edna N. White (Boston: Ginn & Co., 1914, pp. VII+174, pl. 1. figs. 80).—This book presents the fundamental principles underlying the preparation and preservation of foods. The subject-matter is illustrated by numerous laboratory and cooking experiments. Considerable attention is also given to food requirements, selection of foods, and the relative nutritive value and cost of different food materials. The different cuts of meat are well illustrated.

The food industry, edited by K. von Buchka (Das Lebensmittelgewerbe. Leipsic: Akadamische Verlagsgesellschaft, 1914. vol. 1, pp. II+891+XV, figs. 41).—This is the first volume of an extensive handbook intended for food chemists, representatives of industries and trades, druggists, physicians, veterinarians, food control officials, and judges. The contents are as follows: Human Nutrition, by A. Kreutz (pp. 1-34); General Discussion of Foods, etc., by K. von Buchka (pp. 35-87); Coffee and Coffee Surrogates, by A. Hasterlik (pp. 91-162); Tea, Tea Surrogates, and Paraguay Tea, by A. Hasterlik (pp. 163-199); Cocoa and Chocolate, by A. Kreutz (pp. 201-250); Tobacco, by H. Witte (pp. 251-298); Vinegar, by H. Witte (pp. 301-371); Meat and Meat Goods. Inclusive of Fish, by A. Reinsch (pp. 375-497); Eggs, by A. Reinsch (pp. 499-514); Edible Fats and Oils, by K. Fischer (pp. 517-700); and Brandies and Cordials, by W. Bremer (pp. 703-890).

The discussions include methods of manufacture and analysis, nature of adulterations, and laws pertaining to food control.

New food preparations, H. Wagner (Konserv. Ztg., 15 (1914), No. 47. pp. 309, 310).—A summary and digest of data including information regarding commercial products made from bananas, soy beans, malt extracts, gelatin, lecithin preparations, etc.

The egg from the point of view of nutrition, M. L. Delaye (Bul. Soc. Salubrité, Prov. Liége, 16 (1913), pp. 67-89).—This paper discusses in detail the structure and chemical composition of eggs, the changes which they undergo during storage, standards for judging freshness, methods of preservation. food value, consumption in different countries, and methods of judging and sale adopted in the egg-market of Maestricht and other large distributing centers.

[Examination of shellfish] (Maine Sta. Off. Insp. 66 (1915), pp. 8).—The data given regarding a large number of samples of oysters, scallops, and clams include the price paid, the weight as purchased, and the percentage of free

liquids and dry solids. The circular also contains Information concerning the rules which control the sale of shellfish in the State.

Notes on flour—(1) acidity of flour, (2) natural and artificial bleaching of flour, (3) sulphates and lime in flour, R. T. Thomson (Analyst, 39 (1914), No. 465, pp. 519–529).—Analytical data are presented from which the following conclusions are drawn:

The apparent acidity of flour is not due to free lactic acid. The theory that natural bleaching by exposure to the atmosphere is similar to artificial bleaching by nitrogen peroxid has not been proved, but evidence is presented to prove that nitrous acid is not the active agent in bleaching flour exposed to the atmosphere. It also seems probable that artificial bleaching takes place before any formation of free nitric and nitrous acids.

A method for determining sulphates in flour is described, and some analytical data are also given.

Bulbs of very doubtful value as food, D. I. MURPHY (U. S. Dept. Com., Com. Rpts., No. 4 (1915), p. 61).—Chemical analysis of bread prepared from a mixture of two-thirds wheat flour and one-third powdered tulip or crocus bulbs showed that the nutritive value of the wheat was lessened by the admixture. Among the objections made to the use of these bulbs as a food is the fact that they may easily be mistaken for the poisonous narcissus bulb.

Comparative cooking qualities of some of the common varieties of apples grown in Oregon, Ava B. Milam and Harriet B. Gardner (Oregon Sta. But. 124 (1915), pp. 36. ftgs. 19).—The object of this investigation was to determine the relative value of a number of varieties of apples for cooking and some of the general principles underlying the cooking properties. It was also desired to study the relationship of cooking in general to the dessert quality of the apple and to determine whether or not differences in cooking quality are associated with differences of morphology and cell structure. The apples were made into sauce, pies, dumplings, jelly, and marmalade, and the products scored according to standards which are described. As a result of these tests, which were made with 71 varieties of apples, the following general conclusions are drawn:

"Different varieties of apples must be used for certain specific cooking purposes in order to obtain the best product.

"The size of fruit makes but little difference in the cooking quality of apples for sauce. Fruits that are at their prime or even a little overripe are apparently best for sauce.

"There is comparatively little correlation between the scores of apples for sauce and those of the same varieties for jelly. This indicates that the flavor and texture of the jelly are almost entirely dependent upon the chemical composition of the apple rather than its texture and morphological structure.

"Good dessert apples do not necessarily make equally good products when cooked.

"Apples belonging to the same pomological group tend to have similar cooking qualities.

"The sauce-cooking qualities of an apple vary inversely with the proportion of pith area and vascular tissue present, . . . directly as the size of cell, and inversely as the cell cohesion."

Honey and its uses in the home, Caroline L. Hunt and Helen W. Atwater (U. S. Dept. Agr., Farmers' Bul. 653 (1915), pp. 26, fig. 1).—This publication contains some information of general interest regarding honey, but is chiefly devoted to the food value of honey, the economy of honey as a food, and its use in the home, especially in cookery. A large number of recipes are given for the use of honey in the making of bread, muffins, cakes, cookies, desserts, etc.

Ice cream (Maine Sta, Off, Insp. 63 (1914), pp. 141-152).—Standards are given for different kinds of ice cream and the results presented, in tabular form, of the examination of samples collected throughout the State during the year 1914. A statement by A. M. G. Soule is appended.

Maté tea, R. Brieger (Pharm. Zentralhalle, 55 (1914), No. 48, pp. 975-978).—Comparative analyses of coffee, tea, and South American maté tea are reported. The author claims a higher mutritive value for maté tea [Paraguay tea], and recommends its use in the German Army in preference to coffee, tea, and lecithin preparations for producing a temporary stimulating action.

Drugs (Maine 8ta, Off, Insp. 61 (1914), pp. 89-104).—Analyses are given of a number of samples of drugs. The statement is made that about one-half of the simpler preparations analyzed differed more than 10 per cent from the required standard. This is believed to be the result of carelessness rather than an attempt to perpetrate fraud. A statement by A. M. G. Soule is appended.

Miscellaneous food materials (Maine Sta, Off. Insp. 65 (1914), pp. 165-176).—General and specific data are reported regarding the inspection and analysis of a number of samples of miscellaneous food products.

The value and purpose of animal experimentation in meat examination, M. MÜLLER (Ztschr. Infektionskrank. u. Hyg. Hansliere, 16 (1914), No. 3, pp. 115-138).—From the results of his own investigations regarding the toxicity of meat and evidence obtained by other workers, the author concludes that animal (mice) feeding experiments should supplement the chemical and bacteriological examination of meat. Among the reasons advanced in support of this contention is that the presence or absence of certain food poisons can not be determined otherwise than by feeding experiments.

The bacteriology of paper dishes, Mary Dudderidge (Housewires League Mag., 5 (1915), No. 1, pp. 12-15, figs. 3).—This article embodies the results of a study of wood, wood pulp, and water-proof paper food containers. Special attention was given to the study of the bacterial and mold content of these containers.

A study of fruit-jar caps, Gail M. Stapp (Mo. Bul. Ind. Bd. Health, 17 (1914), No. 9, pp. 100, 101).—The results are reported of a comparative study of the old style glass-lined zinc caps which close the jar by pressing tightly on a rubber ring placed on the shoulder of the jar, and a newer style cap in which the rubber ring is placed on the edge of the glass neck of the jar so that the closure is made by the inside glass lining of the cap. Into jars sealed with the old style caps were placed 100 cc. of each of the following solutions: One-half per cent of phosphoric acid. 1 per cent of phosphoric acid. 1 per cent of acetic acid. 1 per cent of acetic acid, 1 per cent of acetic acid, and ½ per cent of nitric acid and 1 per cent of nitric acid. Other jars of the same kind but sealed with the new caps contained like amounts of the same solutions.

After all jars had been inverted and allowed to stand for 6 months it was noted that all the old style caps were corroded. The contents of 5 out of 7 of the jars sealed with the old caps were turbid, showed a decided loss in volume, and contained zinc. The contents of the jar sealed with the newer style caps showed no loss in volume and no turbidity, and contained no zinc, and the caps were not corroded.

Experiments in cheap catering, EDITH SELLERS (Nineteenth Cent. and After, 76 (1914), No. 453, pp. 1123-1137).—This article describes two low-priced restaurants or food shops, one in Christiana and one in Vienna.

The Norwegian establishment has been gradually developed since 1857, when a group of business men started a restaurant to provide wholesome food for laboring people at a price which would pay the total cost of buying, preparing,

and serving the food, plus a reasonable return on the capital invested. It was not a success until a department was introduced for the sale of food, both raw and cooked, to be consumed at home, which made possible the purchase of all supplies at wholesale rates. Since then the patronage has steadily increased until over 1.500 persons get their dinners there, 700 go to the cooked-food department, and several hundred others take minor meals in the café or purchase uncooked provisions. Table d'hôte dinners are served at noon in the dining room at the rate of 13.5 and 9 cents.

The People's Kitchens in Vienna have been in operation since 1872 and have served as the models of the Alexandra Trust Dining Rooms in London and similar organizations elsewhere. They now operate restaurants and food shops all over Vienna and serve low-priced, well-prepared meals to 22,000 persons daily, besides providing 5.420 bunches for school children and selling food to several thousands who eat at home. The business, which is entirely self-supporting though managed by a philanthropic association, is so organized that it can at short notice cater to 10,000 unexpected persons. The association is called out in emergencies, such as inundations, epidemics, or other disasters in any part of the country, to take charge of the feeding of the district affected, and is able to respond immediately to such demands.

A shop-girls' restaurant, Edith Sellers (Cornbill Mag., n. ser., 37 (1914), No. 221, pp. 656-665).—The establishment described in this article is in the heart of the business center of Copenhagen and serves low-priced meals to from 1,200 to 1,800 shop girls, besides selling cooked food. It occupies two floors of a large building, the lower devoted to a la carte service and the upper to table d'hôte dinners. The proceeds are sufficient to cover all expenses, including rent and reasonable returns to the two women who have been entirely responsible for the management, but do not allow of further profits.

Food for polar explorers (Sci. Amer. Sup., 79 (1915), No. 2037, pp. 36, 37).—An abstract is given of an article by Sir Ernest Shackleton in which data are given regarding the food supply and diet of explorers in polar regions.

The diet of working men and the principles of nutrition, F. Hirschfeld (Berlin, Klin, Wehnschr., 51 (1914), No. 42, pp. 1721–1725).—A summary and digest of data which considers principally the use of protein and carbohydrate in the diet.

What are the proximate principles in nutrition? T. Hough (Va. Med. Semi-Mo., 19 (1915), No. 19, pp. 471-475).—A summary and digest of data with particular reference to the importance of amino acids and vitamins in the diet.

The use of boiled milk in infant feeding, R. H. Dennett (Jour. Amer. Med. Assoc., 63 (1914), No. 23, pp. 1991–1995).—Clinical observations are reported upon infants fed with boiled and unboiled milk. The conclusions drawn by the author are in part as follows:

"The prolonged use of boiled milk if properly administered does not necessarily cause nutritional disorders such as rickets, anemia, malnutrition, or poor musculature. Scurvy may be avoided when boiled milk feedings are given, by the administration of orange juice. Boiled milk does not cause digestive disturbances in normal infants [but] aids in overcoming digestive disturbances. The change from boiled milk to unboiled milk may or may not cause digestive disturbances. Boiled milk is probably more apt to cause constipation than unboiled milk, but in certain cases the constipation may be overcome while on boiled milk, although it is not always overcome when the boiling is stopped. The evidence is not conclusive whether the value of the milk is lessened by boiling or not."

Tri-calcium phosphate as a bone former for nursing infants, E. Schloss and L. Frank (Biochem. Ztschr., 60 (1914), No. 5-6, pp. 378-394, figs. 2: abs. in

Zentbl, Physiol., 29 (1914), No. 3, p. 133).—According to the authors, children, both naturally and artificially fed, were able to utilize tri-calcium phosphate taken with cod liver oil.

The etiology of beri-beri with reference to the total phosphorus metabolism, H. Schaumann (Arch. Schiffs u. Tropen Hyg., 14 (1910), Beihefte 8, pp. 397, pls. 12, figs. 2).—In this book the work of others is extensively reviewed and summarized, and the author presents a large amount of original experimental data.

Various theories regarding the etiology of the disease are briefly presented and discussed.

Etiology of beri-beri, II, H. SCHAUMANN (Arch, Schiffs u. Tropen Hyg., 18 (1914), Beihefte 6, pp. 7-258).—Continuing the above work, the author reviews a large number of metabolism experiments with laboratory animals (rabbits and pigeons).

On feeding preparations of maize and rice treated in different ways, it was found that the nitrogen balance in beri-beri was negative, indicating a loss of body protein. The total phosphorus balance was negative, and the phosphorus content of the urine was below the normal value.

A study of "antineuritic" substances of natural occurrence led to the conclusion that beer yeast was the most active and rice polishings the next active in preventing the disease. Moreover, the antineuritic property seemed to vary according to the method of preparation.

It is the opinion of the author that the antineuritic substance occurs in foods in very stable compounds and may pass directly into the blood stream of some animals without simplification.

A review of the literature of phosphorus compounds in animal metabolism, E. B. Forbes and M. Helen Keith (Ohio Sta. Tech. Bul. 5 (1914), pp. 748).—This extensive digest of the literature of phosphorus metabolism has been noted editorially (E. S. R., 32, p. 601).

The value of the calcium balance as an index of calcium metabolism, N. Schoorl (*Pharm. Weekbl., 51* (1914), No. 39, pp. 1216–1219).—A digestion experiment is described in which the amounts of calcium in the food ingested and in the body excretions was determined. In the experimental period of five days the amount of calcium ingested was 10.14 gm, and the amount excreted in the urine and feces 10.11 gm.

Analytical methods and experimental technique are described in detail.

The influence of the melting point of nonemulsified fats on the rate of leaving the stomach, A. von Fejer (Biochem. Ztschr., 53 (1913), No. 1-2, pp. 168-178, fig. 1; abs. in Zentbl. Physiol.. 29 (1914), No. 2, p. 82).—Various fats used in feeding experiments were at intervals removed from the stomach and analyzed to determine the amount which had not passed into the intestine. It was found that the higher the melting point and the greater the viscosity the longer the fats remained in the stomach. The nonemulsified fats left the stomach more slowly than the fat emulsions.

Contributions to the physiology of the stomach.—XXI. The supposed action of the bitter tonics on the secretion of gastric juice in man and dog, A. J. Carlson et al. (Jour. Amer. Med. Assoc., 64 (1915), No. 1, pp. 15-17).— Experiments carried out with men and dogs indicated that bitter tonics acting in either the mouth or stomach have no influence on the secretion of gastric juice, and, as a result of this, on gastric digestion.

The ferments of the pancreas.—III, The properties of trypsin, trypsinogen, and enterokinase, J. Mellanby and V. J. Woolley (*Jour. Physiol.*, 47 (1913), No. 4-5, pp. 339-360).—In continuation of experiments previously reviewed (E. S. R. 29, p. 662), the authors report considerable information on the prop-

erties of these enzyms and their relations to the conditions prevailing during the processes of digestion.

Trypsin may be preserved for a considerable length of time at 38° C, by salts of the alkaline earth metals, particularly those of calcium. In weakly alkaline solution (sodium carbonate 0.16 normal) trypsin is readily destroyed, but in the presence of free acid (hydrochloric acid 0.025 normal) a small amount of trypsin remains undestroyed even after boiling for five minutes. Albumin, peptone, and amino acids protect trypsin against heat destruction, albumin being most effective in this respect.

Trypsinogen is preserved indefinitely at room temperature in the presence of 0.16 normal sodium carbonate solutions, though it is destroyed by heating in this medium to 65° for five minutes. After heating to 100° for five minutes in the presence of hydrochloric acid (0.025 normal) over 30 per cent remains undestroyed. Neutral salts raise the heat of destruction in varying degrees.

Enterokinase is immediately destroyed by free hydrochloric acid (0.01 normal) at 16°. The presence of calcium chlorid (0.5 normal) increases the heat destruction temperature to 75°.

"Enterokinase and trypsin are destroyed by the hydrochloric acid of gastric juice, but trypsinogen is not acted upon. Trypsinogen is destroyed by pepsin and hydrochloric acid. Trypsin has no effect on enterckinase or trypsinogen. Enterokinase has no effect on trypsin, but activates trypsinogen. Pepsin is destroyed by the alkali of pancreatic juice."

The ferments of the pancreas.—IV, Steapsin, J. Mellanby and V. J. Woolley (Jour. Physiol., 48 (1914), No. 4, pp. 287-302).—Continuing the above work, the authors report experimental data which may be summarized as follows:

"The stability of steapsin in alkaline solution is similar to that of trypsin." The loss of steapsin by fresh pancreatic juice increases rapidly with an increase in temperature above 40° C., all of it being destroyed within five minutes at 60°.

The stability of steapsin in acid solution depends upon the concentration of hydrogen ions in the solution, it being stable in the presence of large amounts of higher fatty acids but quickly destroyed by small amounts of free mineral, acids.

"Steapsin can not exist in the presence of free trypsin. Therefore, when pancreatic juice is activated by enterokinase, as trypsin develops steapsin disappears. This fact affords an explanation for the presence of trypsinogen rather than trypsin in fresh pancreatic juice."

Steapsin is protected from destruction by the addition to activating pancreatic juice of serum or egg albumin.

"The action of steapsin on fat is greatly augmented by bile and bile salts. Electrolytes, such as neutral salts, have no influence on the reaction . . .

"From a consideration of the properties of steapsin and its relation to trypsin it appears that steapsin consists essentially of protein; that the destruction of trypsin in alkaline solution is not due to autodigestion but to its inherent instability; that although the conditions in the small intestine which favor trypsin production are inimical to the continued existence of steapsin, yet the presence of protein in a dietary may facilitate fat digestion by virtue of the capacity of the protein to absorb the first formed trypsin."

The influence of sugar injections on heat regulation, H. FREUND and E. Schlagintweit (Arch. Expt. Path. u. Pharmakol., 76 (1914), No. 5-6, pp. 303-310; abs. in Zentbl. Physiol., 29 (1914), No. 2, p. 94).—The authors conclude from experimental data that the nervous systems for heat regulation and for sugar combustion are entirely independent.

The influence of salts on respiratory metabolism, W. Mäder (Untersuchungen über den Einfluss von Salzen auf den respiratorischen Stoffwechsel. Inaug. Diss., Giessen. 1913, pp. 31; abs. in Zenlbl. Physiol., 29 (1914). No. 2, p. 89).—The values are given of respiratory quotients determined for diets containing various inorganic salts.

Metabolism experiments carried out under decreased partial pressure of the oxygen in the air breathed, M. Bache (Stoffwechselversuche bei Herabselzung des Sauerstoff-Partialdruckes in der Respirationsluft. Inaug. Diss., Univ. Halle, 1913; abs. in Zeutbl. Physiol., 29 (1914), No. 2, p. 88).—A decreased partial pressure of oxygen produced changes in metabolism. Long-continued maintenance in this atmosphere induced a certain nitrogen rejention, which continued, however, only under these conditions. Maintenance for a few hours each day in oxygen-poor air led to a prolonged disturbance of protein metabolism.

The kinetic system, G. W. Crile (*Proc. Amer. Phil. Soc.*, 53 (1914), No. 215, pp. 263-286).—On the basis of a large amount of clinical and experimental data the author has formulated a theory to explain the conversion of latent energy into kinetic energy. Quotations follow:

"To become adapted to their environment animals are transformers of energy. This adaptation to environment is made by means of a system of organs evolved for the purpose of converting potential energy into heat and motion. The principal organs and tissues of this system are the brain, the suprarenals, the thyroid, the muscles, and the liver." "The brain is the great central battery which drives the body; the thyroid governs the conditions favoring tissue exidation; the suprarenals govern immediate exidation processes; the liver fabricates and stores glycogen; and the muscles are the great converters of latent energy into heat and motion. . . . Each is a vital link—each plays its particular rôle and one can not compensate for the other. A change in any link of the kinetic chain modifies proportionately the entire kinetic system, which is no stronger than its weakest link."

A respiration incubator for the study of the energy metabolism of infants, J. R. Murlin (Amer. Jour. Discases Children, 9 (1915), No. 1, pp. 43-58, figs. 7).—An apparatus is described which is designed for the study of the metabolism of infants. The respiration chamber is large enough to contain an infant one year of age and is maintained at constant temperature by use of an electric heater and cooling coils contained in the air space which surrounds the chamber. Ventilation and measurement of the respiratory quotient are accomplished by a closed system for removing the water vapor and carbon dioxid produced. Oxygen, to replace that consumed by the infant, is admitted automatically by magnetic devices operated by a spirometer. The muscular activity of the infant is measured by means of tambours connected by rubber tubing with recording devices.

Control experiments with diabetic dogs and alcohol experiments showed an average error in the respiratory quotient for all of the daily averages of 1.8 per cent.

ANIMAL PRODUCTION.

Live stock genetics (Jour. Heredity. 6 (1915), No. 1, pp. 21-31, figs. 5).— This is a review, by the research committee on animal breeding of the American Genetic Association, of the work in experimental animal breeding now under way at the various state experiment stations.

[Bibliography on animal breeding] (Ztschr. Induktive Abstam. u. Vererbungslehre, 13 (1914), No. 1-2, pp. (12)-(21), (23), (24)).—A bibliography of new literature on animal breeding, heredity, anatomy, and physiology.

Prepotency, E. N. Wentworth (Jour. Heredity, 6 (1915), No. 1, pp. 17-20).—The author contends that the first essential of prepotency is homozygosis in a dominant character. This is opposed to the general belief that prepotency is a quality belonging to individuals rather than characters. He states that "as a matter of fact it is highly improbable that there ever occurred the ideally prepotent animal described by the breeder; that is, one which is able to impress most of his characters upon his progeny in spite of the females to which he is mated. . . . Prepotency is never a property of the individual, but belongs to a certain few characters that are part of the hereditary makeup of the individual, and their condition as to homozygosis or heterozygosis is the entire determining factor. The degree by which one animal is more 'strongly bred' for a character than another animal is this wide degree of purity or hybridity."

The author believes that prepotency is not entirely a property of the male sex, as many breeders contend, but exists in both sexes. It is thought that the linkage or coupling of separate factors in heredity explains observed prepotency and the difference between "breeders of breeders" and "breeders of performers."

Variability of cattle, J. H. W. T. REIMERS (Jahrb. Wiss. u. Prakt. Tierzucht, 9 (1914), pp. 132-162, figs. 6).—This reports a biometrical study made of the body measurements of 300 Holstein cows from 2\frac{1}{3} to 3 years old.

The effect of lead on the germ cells of the male rabbit and fowl as indicated by their progeny, L. J. Cole and L. J. Bachhuber (*Proc. Soc. Expt. Biol. and Med., 12 (1914), No. 1. pp. 24–29).*—In these studies it was demonstrated that the offspring produced by male rabbits which have been poisoned by the injection of lead acetate into the alimentary tract have a lower vitality and are distinctly smaller in average size than normal offspring of unpoisoned males. Similar results were obtained with fowls.

On the ovarian factor concerned in the recurrence of the estrous cycle, F. H. A. Marshall and J. G. Runciman (Jour. Physiol., 49 (1914), No. 1-2, pp. 17-22, figs. 2).—The authors conclude from their experiments that "the occurrence of 'heat' (proestrum and estrus) in dogs does not depend upon the presence of mature (or nearly mature) Graafian follicles in the ovaries. It is equally evident that it is not dependent upon corpora lutea. It must be supposed, therefore, that the ovarian factor in the recurrence of 'heat' resides in some other ovarian element or combination of elements. The ovarian interstitial cells are possibly concerned in the process, but cyclical changes in the condition of these cells have not so far been observed in the dog's ovaries.

"The view which has generally been maintained that the ripening of the Graafian follicles and the onset of menstruation or heat stand to one another in the relation of cause to effect, must be finally abandoned. It is probable that both series of changes are effects of some more deep-seated ovarian phenomenon."

Studies in the blood relationship of animals as displayed in the composition of the serum proteins.—III, A comparison of the sera of the hen, turkey, duck, and goose with respect to their content of various proteins. W. B. Thompson (Jour. Biol. Chem., 20 (1915), No. 1, pp. 1-6).—In continuation of work previously noted (E. S. R., 28, p. 875; 30, p. 68), the author has determined the average percentage of insoluble globulin, total globulin, and total albumin in the sera of the hen, rooster, turkey, duck, and goose.

Studies in the blood relationship of animals as displayed in the composition of the serum proteins.—IV, A comparison of the sera of the pigeon, rooster, and guinea fowl with respect to their content of various proteins

in the normal and in the fasting condition, R. S. Briegs (Jour. Biol. Chem., 20 (1915), No. 1, pp. 7-11).—This continues the above, giving the average percentage of the various proteins in the sera of the pigeon, rooster, and guinea fowl during normal and fasting periods.

The weights of newborn calves, sheep, goats, and pigs, J. RICHTER and A. BRAUER (Jahrb. Wiss. u. Prakt. Tierzucht, 9 (1914), pp. 91-131, pls. 2).—This article reports studies made of the weights of newborn calves, sheep, goats, and pigs, comparing the initial weight with their aftergrowth. A bibliography of 42 references is included.

Texas feeding stuffs; their composition and utilization, G. S. Frans (*Texas Sta. Bul. 170 (1914)*, pp. 34).—This bulletin contains a discussion of the composition of Texas feeding stuffs, their utilization and values, the calculation of balanced rations, and tables showing the composition, coefficients of digestibility, and feeding values.

Sugar as a feed stuff, F. Lehmann (Ztschr. Landw. Kammer Braunschweig., 83 (1914), Nos. 34, pp. 360-362; 35, pp. 367-369; abs. in Mitt. Ver. Deut. Schweinezüchter, 21 (1914), No. 23, pp. 398-401).—Successful experiments are reported in which swine were fed from 0.25 to 0.5 kg. of sugar per day, together with a grain ration. It is estimated that the sugar effected an average gain of 0.332 kg. per kilogram of sugar fed. It is thought that the sugar raises the digestibility coefficient of the entire ration.

[Fish as a cattle food] (Nature [London], 94 (1914), No. 2355, p. 430).—It is stated that in Shetland and Iceland, dry salt fish is fed to cattle, sheep, and horses. Early experiments by Lawes are cited which demonstrated that fish-fed pigs were fat and well ripened. Heifers which had been on fish diet for six months showed an average increase of weight of 54 lbs. per head as against 70 lbs. for normally fed animals.

The use of fish as cattle food, R. C. Wood (Agr, Jour. India, 9 (1914), No 4, pp. 356-361).—It was demonstrated that the addition of $\frac{3}{4}$ lb. of ground fish to a basal ration of rice bran when fed to heifers increased their weight practically as much as an ordinary feed. No ill effects followed the addition of fish to the ration for cattle and after a little time no trouble was experienced in getting the cattle to eat it freely. As a fattening feed, it was found not to compare favorably with peanut meal.

The question of the digestibility of turf, S. Gov (Landw. Jahrb., 46 (1914), No. 3, pp. 403-408).—The author reviews investigations on the digestibility of turf and shows wherein it has a depressing influence on the digestibility of the nutrients, the ferments being rendered less efficient when a large quantity of this material is fed.

[Analyses of feed stuffs], R. E. Rose (Ann. Rpt. State Chem. Fla., 1914, pp. 107–135).—Analyses are reported of cotton-seed meal, beef scrap, bran. middlings, dried beet pulp, velvet beans, oats, chops, wheat. Para grass hay dried distillers' slop, shipstuff, molasses feed, alfalfa meal, shorts, linseed meal, rice meal, and various mixed and proprietary feeds.

Commercial feeds, J. M. PICKEL (Bul. N. C. Dept. Agr., 35 (1914), No. 10, pp. 73).—Analyses are reported of wheat bran, middlings, shorts, red dog flour, shipstuff, molasses feed, corn, cracked corn, corn chops, corn bran, gluten feed, beet pulp, rice meal, rice polish, rice bran, wheat, oats, wheat screenings, floor sweepings, and various mixed and proprietary feeds.

[Report of] department of animal husbandry (Oregon Sta. Rpt. 1913-1914, pp. 21, 22).—In an experiment comparing skim milk and tankage as supplemental feeds for swine, equal nutrients being fed, lot 1 made a total of 669 lbs. gain, consuming 2.72 lbs. of barley and 6.31 lbs. of skim milk per pound of

gain; and lot 2, 608 lbs. gain, consuming 3.31 lbs. of barley and 0.35 lb. of tankage per pound of gain. The cost per pound of gain in lot 2 was 5.84 cts. The value of skim milk for each pound of gain in lot 1 as compared with lot 2 was 28.29 cts.

Two lots of pigs fed a ration of crushed wheat, bran, and tankage, 5:4:1, lot 1 being self-fed on dry feed and lot 2 hand-fed on soaked feed, required per pound of gain 5.12 lbs. and 4.88 lbs., respectively. In a second trial lot 1 consumed 4.18 lbs. of feed and lot 2, 5.37 lbs. of feed per pound of gain. In this experiment the self-feeder lot ate more feed daily and gained more rapidly at a small cost of nutrients than did the hand-fed lot.

Two Duroc Jersey sows with 7-day-old pigs consumed during the time of suckling the pigs 1,220 lbs, of a feed mixture composed of wheat, shorts, and tankage 5:4:1, while the 15 pigs consumed from April 1 to August 15, 3,436.3 lbs, of the feed, representing a total value of \$122.68, or 8.74 cts, per pound of live weight of pigs, estimating the birth cost of the pigs to be \$3.

In an experiment to determine the practicability of utilizing cull ewes for the production of early market lambs, 20 such ewes were fed during the winter in an open yard with a shed, the lambs arriving at irregular intervals. Thirteen lambs averaging 40 lbs. live weight were sold the first part of April and the seven remaining 70-lb, lambs were sold the latter part of June. The ewes cost \$82.42 and the feed \$149.68. After the sale of ewes, lambs, and wool, a loss of \$40.59 had been realized.

One lot of five lambs allowed the run of the entire farm during the winter (December 3 to March 4) and fed in troughs and racks in the open field made an average gain per head of 27.75 lbs., while another lot of six lambs kept in a shed with access to a small outside yard well bedded with straw made an average gain per head of 23.25 lbs. The lambs under shelter did the better during the rainy season, but during good weather the best results were obtained from those outside.

Comparative efficiency for growth of the nitrogen of alfalfa hay and corn grain, E. B. Hart, G. C. Humphrey, and F. B. Morrison (Wisconsin Sta. Research Bul. 33 (1914), pp. 87-107, figs. 4).—After reviewing the work of previous investigators, an account is given of two years' experimental work. The purpose of the experiments was to determine the rate of nitrogen retention by growing heifers when the source of the nitrogen in the ration was mainly either the corn grain or the whole alfalfa plant.

During 1910-11, two Holstein heifers were fed by the reversal method for 16 weeks, one animal receiving 5 lbs. corn meal, 2 lbs. gluten feed, and 7 lbs. corn stover, and the other 3 lbs. corn stover, 5 lbs. alfalfa hay, 3 lbs. alfalfa meal, and 4.2 lbs. starch.

During 1911–12, two Holstein heifers were fed as before, except that in this case the second heifer in each case received 5 lbs. alfalfa hay, 4 lbs. alfalfa meal, and 5 lbs. starch. The nutritive ratios of the two rations, based on crude digestible protein, were practically the same, but if in the case of the hay the "amid nitrogen" be excluded, then the nutritive ratio becomes 1:12.4. The efficiency of the two rations for growth, based on the nitrogen storage, was essentially the same.

It is concluded from the results obtained that "on the basis of total nitrogen ingested, the utilization of nitrogen for growth was as efficient when the source was from alfalfa hay as when it came from the corn kernel. With high intake of total digestible crude protein, which in the case of alfalfa includes the amid nitrogen, the storage of nitrogen was essentially alike on the two rations.

"There was no sudden decrease or increase in the nitrogen content of the urine or feces when the animals were suddenly changed from one ration to the other. This is evidence that the amid nitrogen was being used in the same way as the true protein nitrogen. It is apparent from our data that full value, at least for growth, can be given to the total nitrogen of alfalfa hay. The amid nitrogen should not be considered worthless. . . . With growing heifers there was no very concordant rise in creatinin output with increased storage of nitrogen. This precludes the possibility of using this index for these animals as a measure of the efficiency of a given source of nitrogen to produce nitrogen storage."

Steer feeding experiments, W. H. Tomhave and C. W. Hickman (Pennsylvania Sta. Bul. 133 (1914), pp. 245-272, figs. 10).—Five lots of 12 two-year-old steers, each weighing approximately 900 lbs, per head, were fed during two periods of 56 and 84 days, respectively, with the following results:

| Average daily feed per steer. | per | md | Jo |
|-------------------------------|---------|------|-----|
| | garin - | lod. | n T |

Summary of steer-feeding experiments.

| | Average dully feed per steer. | | | | | | | | | od ı | ин | 5 | | pay |

a 56 days.

b 28 days.

It is concluded that "corn silage at \$3.50 per ton is slightly more economical when used as the sole roughage for steers, than a combination of mixed hay and silage in which the silage is limited to 20 lbs, per head daily when hay. costing \$12 per ton, is freely fed.

"A ration of mixed hay and corn stover as roughage, with broken ear corn. or corn-and-cob meal, and bran as grain, when fed throughout the entire feeding period, is not economical in Penusylvania. The cattle fed this ration through the entire feeding period produced 100 lbs, of gain at an average cost of \$12.97, while those receiving no grain during the first 56 days except cottonseed meal and what grain was present in the silage, made 100 lbs, of gain at the average cost of \$10.48. Wheat bran as a source of protein at \$25 per ton is much more expensive than cotton-seed meal at \$34 per ton. The additional cost of grinding corn is not repaid by greater gains from steers.

"Alfalfa hay at \$15 per ton, when fed at the rate of 5 lbs. per 1,000 lbs. live weight, in combination with corn silage, is not so efficient as a source of protein as 2½ lbs. of cotton-seed meal per 1,000 lbs, live weight daily at \$34 per ton. The feeding of 5 lbs, of alfalfa hay with $2\frac{1}{2}$ lbs, of cotton-seed meal per 1,000 lbs. live weight daily as a source of protein in a ration of corn silage and

corn is not now economical. Alfalfa hay fed in combination with corn silage during the first 56 days, with corn added to the ration for the balance of the period, reduced the cost of gains, but also decreased the rate of gain as compared with the ration differing by the addition of cotton-seed meal.

"Corn silage at \$3.50 per ton as the sole roughage is more economical than corn silage and alfalfa hay combined when alfalfa hay costs \$15 per ton.

"The cost of producing a pound of gain was considerably less during the first period, when roughage only was fed, than during the second period, when grain also was fed.

"Cattle receiving no corn silage but fed corn from the beginning of the experiment consumed more dry matter daily than those fed corn silage without corn."

Cottonseed meal for feeding beef cattle, W. F. Ward (U, S, Dept. Agr., Farmers' Bul. 655 (1915), pp. 8).—This is a popular review of work previously reported from other sources, giving the results of experiments in feeding cotton-seed meal to beef cattle in varying proportions and offering suggestions for its profitable use. "If cotton-seed meal does not cost over \$34 a ton, it can probably be used to advantage in wintering the breeding herd. . . . Cotton-seed cake can be used very profitably as a supplemental feed for fattening cattle on pasture. Five times as many farmers should be using cotton-seed meal as are doing so at the present time."

Jersey-Angus cattle, A. H. Kuhlman (Jour. Heredity, 6 (1915), No. 2, pp. 68-72. figs. 6).—Breeding trials being conducted by F. B. Samuelson in England are reported in which Jersey cows were mated with an Angus bull. The F_1 individuals were mated, as were also the F_2 individuals. The crossbred cows of the F_1 generation showed a high yield of milk and milk fat, their udders were very uniform and good-sized, and they were more hardy than their dams, requiring less close housing during the winter. The F_2 individuals showed marked variations in conformation and color, indicating a segregation and recombination of the characters of the original parents. It is stated that the Jersey-Angus crosses bring as good prices as most beef cattle, and the possibilities of establishing a new breed based upon this cross are being considered.

Shorthorn cattle in Missouri, B. O. Cowan (*Missouri Bd. Agr. Mo. Bul.*, 12 (1914), No. 12, pp. 91, figs. 18).—This is a history of the development of the Shorthorn breed of cattle in Missouri and includes a llst of Shorthorn breeders in that State.

The present status of the cattle industry in Canada, H. S. ARKELL (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 10, pp. 1255-1263).—A statistical review of the cattle industry in Canada, showing the distribution of dairy and beef cattle in the various Provinces, the exports and imports of cattle and beef, and the status of the various record associations.

Cattle raising in the Belgian Kongo, F. Kolbe (Jahrb. Wiss. u. Prakt. Tierzueht, 9 (1914), pp. 208-222, figs. 5).—A general discussion of the native breeds of cattle found in the Belgian Kongo.

The value of castration of Deccan bullocks, J. B. Knight (Dept. Agr. Bowbay Bul. 62 (1914), pp. 6, pls. 2).—In this experiment with Deccan bullocks, it was demonstrated that neither early nor late castration materially affected the weight of the bullocks. There was a greater proportionate development in the hind quarters of early-castrated than of late-castrated animals. The strength and hardiness were not impaired by early castration, while the docility was markedly improved and the activity was greater.

The breeds of sheep of the central Pyrenees, GIRARD (Rev. Vet. [Toulouse], 39 (1914), Nos. 7, pp. 402-412; 8, pp. 460-472; 9, pp. 523-532, pls. 2, figs. 7).—An account of the native breeds of sheep of the central Pyrenees, their breed characteristics, and utility value.

Corriedale sheep in United States (Jour. Heredity, 6 (1915), No. 2, p. 96).—
A brief account of a recent importation of 10 Corriedale rams and 54 ewes, recently made by the U. S. Department of Agriculture from New Zealand. "The breed, which originated in the Province of Canterbury, New Zealand, in the late seventies and was long known officially as 'inbred half-breds,' resulted from a Lincoln × Merino cross and in part from an English Leicester × Merino cross. It interests the stockman because it offers a combination of wool and mutton qualities, and the genetist because it appears to breed fairly true in spite of the short time that has elapsed since its formation. In appearance it is very nearly a blend between the two parents, and there seems to be little segregation of characters in the breed at present."

The sheep-killing dog, V. O. McWhorter (U. S. Dept. Agr., Farmers' Bul. 652 (1915), pp. 13, figs. 3).—It is estimated that the total annual loss in numbers of sheep killed by dogs in 36 farm States, not including the western division, is 107.760 head, which although less than 1 per cent of the total number of sheep in these States, is sufficient to decrease materially the possible profits and to discourage the development of the industry.

From replies received from crop correspondents it is estimated that the present number of sheep in these States can be increased by 150 per cent without displacing other live stock on farms. These replies furthermore indicate that sheep raising is considered profitable but that dogs are the main barrier to keeping them. The author advocates a higher dog tax, thus reducing the number of superfluous dogs, and the adoption of more effective state dog laws. An outline of what is deemed a suitable dog law is suggested. This provides for the taxation of dogs, the identification of licensed dogs, dealing with stray or sheep-killing dogs, and compensation to the sheep owners for losses. An effective dog-proof fence is described.

The age of goats according to their teeth, Scheunpflug (Berlin, Tierärztl. Wchnschr., 30 (1914), No. 28, pp. 503, 504; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases, 5 (1914). No. 10. pp. 1337-1339).—The data found in the literature on the replacing of the teeth in sheep are compared with the author's observations on goats.

It appears that the termination of the period during which the incisors are replaced is nearly the same in goats as in early-maturing sheep. The period between the replacing of the first and second pairs of incisors in sheep is about two months shorter than in goats, but the interval between the second and third pairs is shorter in goats. The temporary molars are replaced earlier in goats than in sheep, in goats shortly before the cutting of the third molar, in sheep only after the cutting of the latter or at the same time.

A detailed description is given of the appearance of the teeth of the goat up to three years of age.

The digestibility of maize consumed by swine, S. C. Guernsey and J. M. Evvard (*Biochem. Bul., 3 (1914*), *No. 11–12, pp. 369–372*).—This is a preliminary report of work conducted during 1909, 1910, and 1911 at the Iowa Experiment Station, in which four lots of five animals each of 12-month-old 200-lb. hogs and of 80-day-old 70-lb. hogs were fed corn in five different forms, and two digestion trials of 10 days' duration made with each lot. The results are summarized in the table following.

Digestion coefficients of corn fed to hogs.

| Method of preparation. | Heavy-weight hogs. | | | | | | | Light-weight hogs. | | | | | | |
|------------------------|---------------------|----------------|------------------------|---|------------------|-------------------|---------------------|--------------------|------------------------|---|-------------------|-------------------|--|--|
| | Dry mat- ter. | Pro- tein. | Ether ex- tract. | Nitro- gen- free ex- tract. | Crude fiber. | Ash. | Dry mat- ter. | Pro- tein. | Ether ex- tract. | Nitro- gen- free ex- tract. | Crude fiber. | Ash. | | |
| Whole grain, on cob | Per ct. 85, 42 | Per ct. 74. 79 | Per ct. 66. 85 | Per ct. 90.67 | Per ct. 19.65 | Per ct. 24, 85 | Per ct. 88, 86 | Per ct. 78, 18 | Per ct. 72, 42 | Per ct. 93, 59 | Per ct. 43. 80 | Per ct. 20. 50 | | |
| Shelled grain, | 86, 48 | 74.39 | 64.22 | 91.56 | 43.46 | 23.88 | 88, 05 | 76,00 | 73.85 | 93.16 | 45, 42 | 7.36 | | |
| Shelled grain, soaked | 85, 40 | 74.51 | 58.18 | 90.66 | 40,85 | 15.98 | 87. 20 | 76, 24 | 62.87 | 92.78 | 45, 17 | 7.32 | | |
| Ground grain, | 87. 25 | 73.14 | 65. 03 | 92.65 | 39.72 | 20, 64 | 87, 22 | 76, 60 | 59,40 | 92.88 | 42.00 | 10.92 | | |
| Ground grain, soaked | 88.39 | 77. 13 | 59.57 | 93.37 | 39.40 | 18.05 | 85, 91 | 70.50 | 67.91 | 92.11 | 38, 92 | - 5. 29 | | |

It is stated that these figures are in close agreement with those obtained in similar experiments at the Ohio Station (E. S. R., 31, p. 268).

In the 1909–1910 series of experiments a correlation between the digestibility and time required for digestion was found, which was shown by the average length of time required for charcoal to traverse the digestive tract. For the light-weight hogs the average time required with the respective feeds was 70.5, 54, 48, 57, and 40.5 hours, the average digestibility of the dry matter being 90.96, 88.8, 88.09, 88.4, and 84.52 per cent, respectively. For the heavy-weight hogs the average time required was 38, 48, 36, 36, and 50 hours, respectively, and the average digestibility of the dry matter was 86.29, 87.04, 84.97, 86.46, and 88.61 per cent, respectively. The 1911 series of experiments do not corroborate these results and hence they are not taken as conclusive.

These digestion trials agree fairly well with former feeding trials (E. S. R., 22, p. 174) which demonstrated that light-weight hogs weighing less than 200 lbs, make the most rapid gains with whole corn on the cob, in the natural state, while heavy-weight swine make the most rapid gains with the soaked shelled and soaked ground grain.

[Swine-feeding experiments], M. Popp and W. Felling (Deut. Landw. Presse, 41 (1914), No. 82, pp. 901, 902).—In an effort to find suitable substitutes for barley in the fattening ration, 8 lots of 110-lb. pigs were fed 80 days as follows: Lot 1, fish meal and barley meal, lot 2, fish meal and barley meal with steamed potatoes, lot 3, corn-blood feed and barley meal with steamed potatoes, lot 4, yeast and barley meal with steamed potatoes, lot 5, yeast, sugar feed, and barley meal, lot 6, fish meal, barley meal, and a proprietary feed, lot 7, fish meal, barley meal, a proprietary feed, and potatoes, and lot 8, fish meal, barley meal, and rye meal.

Considering the gains made, the cost of gain, the quality of the flesh, and the feed requirements, the lots ranked as follows: 2, 7, 3, 8, 6, 1, 5, 4.

The swine-raising industry in Canada, J. B. Spencer (Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 9, pp. 1154–1159).—This is a statistical account of the swine-raising industry of Canada, discussing the early development of the industry and the present status of the export trade, especially of bacon.

It appears that there has been a decline in exports, due largely to the increased consumption in Canada. The exports of hog products have until quite recently been almost entirely to Great Britain, but with the throwing open of the markets of the United States increased quantities of Canadian bacon, hams,

and pork have come to this country. There has been a marked increase in the pedigree registration of the bacon breeds of hogs and a material decrease in the fat-hog breeds during the past few years.

Swine, G. E. DAY (Ontario Dept. Agr. Bul. 225 (1914), pp. 80, figs. 28).—A general treatise on the feeding, care, and management of swine.

The breeds of horses in Norway, C. WRIEDT (Abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 9, pp. 1194–1196).—An account of the origin, development, and breed characteristics of the horses of Norway, one being the native breed known as Fjord, the other a special breed developed in eastern Norway and known as Gudbrandsdal.

[Report of] poultry section (Minnesota Sta. Rpt. 1914, p. 37).—From feeding records kept of a flock of ducks "it would appear that in flocks of 20 or more the feeder would realize about 25 cts. per hour for his time, with increased returns as the number is increased. Ducks, when fed unstintingly, are ready for market in from 9 to 11 weeks."

Records kept of the cost of growing the chick during the fattening age "indicate that at this, the most expensive period of production, the cost of feed exceeds one-half the lowest market price, which in this locality is usually about 16 cts, per pound live weight for prime young stock."

A flock of White Leghorns kept on range and fed by the hopper method doubled in weight in 57 days at a feeding cost of less than 7 cts. per pound gained. "At the low average price of 20 cts. per dozen for the eggs produced, a flock of 39 White Leghorns shows receipts of over 30 per cent above the maximum feeding cost. That a younger flock and one that had been confined for a shorter space of time would have shown a larger egg yield is certain."

[Report of] poultry husbandry department (*Oregon Sta. Rpt. 1913-1914*, pp. 22-24).—It has been found that the humidity surrounding eggs during incubation has a highly important function to perform and that this, taken in connection with ventilation of the incubator and the supply of oxygen, is probably the factor to be reckoned with in solving the problem of losses in connection with the hatching of chickens.

Results of crossbreeding experiments with Plymouth Rocks and Leghorns indicate that it is possible to produce a bird with a higher egg yield than the average of either parent, while the meat quality is also such as better to meet the needs of the consumer.

Experiments on egg laying in different breeds of poultry (Abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 9, pp. 1199, 1200).—In these trials conducted at the Royal Veterinary and Agricultural College at Copenhagen, of the 7 breeds represented the Leghorns took first place for both number and total weight of the eggs. Most hens laid the greatest number of eggs during the first or second year, but there were some that produced more in the third year. As for summer and winter laying, there was no large difference between Plymouth Rocks and Leghorns, the former laying a slightly greater percentage of their eggs during the winter months than the latter. The older hens laid a smaller percentage of their eggs during the winter months than the younger ones.

The weight of individual eggs was greater for Minorcas and Leghorns than for White Wyandottes and Houdans, and appeared to increase with the age of the hens. The weight of the birds increased with age, but only up to the end of the third year, when they were fully grown. There appeared to be a growth from autumn to spring and a sinking from spring to summer. This was especially noticeable in good layers, the body weight of which decreased to a greater extent than that of poor layers during the spring months when egg laying was more active.

Broodiness, which was more frequent among Plymouth Rocks than among Leghorns, was most pronounced in the best layers. It was found that 16 days after mating the hens still laid fertile eggs. When mating was repeated after a period of more than 16 days, the first fertile egg was generally laid 3 days and sometimes 4 days later. It was found possible to influence the color of the eggshell by pairing a cock of a breed which has yellow or brown eggs with a hen of another breed that lays white eggs, or vice versa, the breed of the hen alone being responsible for the color of the eggshell.

Winter egg production, Helen D. Whitaker (Washington Sta. Popular Bul. 76 (1914), pp. 15).—This gives general information on the selection, housing, care, feeding, and management of poultry for winter egg production.

How to care for the little chick, E. L. Andrews (West Virginia Sta. Circ. 11 (1914), pp. 4).—General information on the care of young chicks.

Experimental studies of hybridization among ducks and pheasants, J. C. Phillips (Jour. Expt. Zool., 18 (1915), No. 1, pp. 69-143, figs. 9).—This article reports hybridization experiments in which a study was made of the plumage characters in wild species of birds, this being almost wholly an investigation into the inheritance of male secondary sex-characters.

It was found that characters often apparently clear-cut and antagonistic do not segregate clearly. "There is some evidence that in closely related geographical races there is a nearer approach to orthodox Mendelism, but this is never reached, even in back crosses, except occasionally in isolated characters or in the more undifferentiated plumages of the female sex. In species with unrelated character complexes there are only slight tendencies to a greater variation in F_2 than in F_3 , as is shown in the pintail \times mallard cross, or the Australian \times mallard cross. Such variation, comparable to that seen in size characters, may be explained as the manifestation of factor complexes, outwardly expressed in plumage characters, but not by any means necessarily specific units for these epidermal structures alone. . . .

"Sex-linked inheritance is probably a feature of domestic races in birds. In wild species thus far examined there is no clear evidence of unequal transmission by the sexes. Both sexes can carry the characters of the opposite sex through several generations without an additional 'dose' of the character in question."

Hints on goose culture, Helen D. Whitaker (Washington Sta. Popular Bul. 83 (1915), pp. 4).—General information on the feeding, care, and management of geese.

Some factors affecting the weight, composition, and hatchability of hen eggs, H. Atwood (West Virginia Sta. Circ. 9 (1914), pp. 4).—This is a popular account of material previously reported (E. S. R., 31, p. 270).

A study of the relation of the chemical composition of hens' eggs to the vitality of the young chick, L. J. Cross (Thesis, Cornell Univ., 1912, pp. 16).—In this work the author attempted to determine the relation of the vitality of the chick to the chemical composition of the egg. and to control the composition of the egg. The results are summarized as follows:

"The work on the coloring of the parts of the eggs by feeding dyes to the hen indicates that the fat found in the albumin region of the incubated egg is derived not wholly from the yolk, but from another source, the albumin itself. The percentage of fat in the yolk of the weak chick is in some cases less and sometimes more than in the yolk of the strong chick. The weak chick is equally as rich in phosphorus as the strong chick. The phosphorus content of the egg varies but little. There is no increase in the phosphorus content of the egg

when the hen is fed lnorganic phosphorus. Hens on range do not produce eggs different in composition from those on bare yard.

"There is a variation in the eggs of individual hens in the content of protein and in the content of fat, but the eggs produced by each individual are quite constant in composition. The sum of the percentage of the fat and of the protein in eggs varies but little. In feeding a ration high in fat, or a ration high in protein, there is no material change in the characteristics of the hen as regards the amount of fat and protein in the egg. There seems to be no relation between the protein or fat content of the egg as regards its hatching power or the vigor of the young chick."

An abnormal hen's egg, F. E. Chidester (Amer. Nat., 49 (1915), No. 577, pp. 49-51, figs. 2).—A description is given of a "gourd-shaped" egg having a constricted yolk surrounded by apparently normal albumin. This particular abnormality is thought to have been caused by a constricted oviduct rather than from the fusion of two eggs during apposition, induced by antiperistalsis.

The interior quality of market eggs, E. W. Benjamin (New York Cornell Sta. Bul. 353 (1914), pp. 46, pls. 8, figs. 14).—Topics discussed in this bulletin are the physiology of egg production; the structure of the normal egg; the interior quality of a normal fresh egg; the internal and external factors affecting the interior quality of eggs; and suggestions to producers, dealers, and consumers. A bibliography and several colored illustrations of market eggs are included.

The community egg circle, C. E. BASSETT and W. H. KERR (U. S. Dept. Agr., Farmers' Bul. 656 (1915), pp. 7).—This bulletin contains general information on cooperative egg marketing and gives forms for use in organizing, managing, and auditing a community cooperative egg association.

Sodium silicate as an egg preservative (Minnesota Sta. Rpt. 1914, pp. 26, 27).—It is concluded from two seasons' work that eggs are not appreciably affected within a much larger range of alkalinity than that exhibited by market samples of sodium silicate solution. Deposition of silicate from solution is dependent upon the exposure to air and the amount of carbon dioxid present. Deposited silicate may be redissolved by boiling with a little lye, and such solutions are equal in every respect to fresh solutions.

Fur farming in Canada, J. W. Jones et al. (Ottawa: Com. Conserv., 1914, 2. ed., rev. and enl., pp. IX+278, pls. 28).—A revised and enlarged edition of this work, previously noted (E. S. R., 29, p. 373).

DAIRY FARMING—DAIRYING.

Dairy farming, O. E. Reed (Kansas Sta. Circ. 45 (1915). pp. 26, figs. 9).— This circular contains general information on the dairy breeds, the selection, feeding, care, and management of the dairy herd, together with directions for making the Babcock test.

Dairying in Switzerland, W. WRIGHT (Jour. Agr. [New Zeal.], 10 (1915), No. 2, pp. 140-147, figs. 2).—An account of several of the prominent dairy farms and manufacturing concerns of Switzerland, together with a description of the method of manufacturing Emmental cheese.

On the importance of meadows and pastures for the dairy establishment, O. Laxa (*Milchw. Zentbl.*, 43 (1914), No. 6, pp. 145-153).—The author shows wherein the geological character of the land influences the mineral content of its vegetation and how in turn this affects the mineral content of the milk and its value for cheese making. It is further shown that although the bacterial content of the milk of pasture-fed cows is much lower than that of stall-fed

cows, the bacteria that the milk does contain are of a desirable kind, favorably influencing the flavor and character of the dairy products.

The comparative efficiency for milk production of the nitrogen of alfalfa hay and corn grain, E. B. Harr and G. C. Humphrey (Wisconsin Sta. Research Bul. 33 (1914), pp. 108-119, figs. 3).—This material has been previously reported from another source (E. S. R., 32, p. 74).

Feeding experiment with milch cows, or the value of beer yeast, V. Renner (Wchnschr. Brau., 31 (1914), No. 49, pp. 473-476).—In this experiment fresh beer yeast when fed in quantities of from 12 to 17 kg. (26 to 37 lbs.) per head per day as a supplementary feed to milch cows increased both the milk yield and the milk fat percentage over that obtained by a ration in which either rape seed cake or palm kernel cake was used. The composition of the yeast is given as water 87.92, protein 6.48, fat 0.06, nitrogen-free extract 4.56, fiber 0.14, and ash 0.84 per cent.

The effect of repeated injections of pituitrine on milk secretion, S. SIMPSON and R. L. HILL (Amer. Jour. Physiol., 36 (1915), No. 3, pp. 347-351).—This material has been noted previously from another source (E. S. R., 32, p. 268).

A Danish cow testing association, J. J. Dunne (Hoard's Dairyman, 49 (1915), No. 11, p. 424).—From data presented in the annual report of the cow testing association on the Island of Funen, Denmark, the author concludes that it cost more to produce 1 lb. of milk rich in fat than it did to produce 1 lb. of milk poor in fat, but that 1 lb. of butter was more cheaply produced from the milk rich in fat.

The average Jersey cow consumed about 1,000 feed units less than the average red Danish cow, and yielded 22 lbs. more of butter per year. The Jersey was the more economical butter producer, but the red Danish with a 3.3 milk fat percentage was the more economical as a milk producer.

In milking a cow on different occasions and from different teats it was found in a single milking the first streams contained 0.25 per cent of fat, this increasing until the last few streams tested 9.4 per cent.

Data are presented showing the remarkable improvement that has been made during the past ten years in the producing capacity of the dairies under the stimulus of the cow testing association.

Rules and regulations governing the operation of the Babcock test (*Iowa Dairy and Food Com. Bul. 11* (1915), pp. 6).—General information on the use of the Babcock test.

Coming standards of market milk, G. L. Noble (Milk Dealer, 4 (1915), Nos. 5, pp. 32-35; 6, pp. 14-18).—A discussion of the milk standards of the various cities and the tendency toward more rigid municipal control.

The bacteriological control of public milk supplies, W. D. Frost (*Trans. Wis. Acad. Sci., Arts, and Letters, 17* (1914), pt. 2, No. 6, pp. 1305-1365, pls. 2, flgs. 8).—After a detailed description of the bacteriological methods of milk analysis used, the author discusses the results of his studies of the different grades of milk obtained from various sources. Under winter conditions the raw milks had an average bacterial content of 2.000,000 per cubic centimeter, those pasteurized in bottles 532,000, inspected milk 159,560, and certified milk 20,000.

The number of colonlike bacteria, i. e., those fermenting lactose with the formation of gas, were found in the various grades of milk in the order: Raw milk, inspected milk, certified milk, and pasteurized milk. *Bacterium welehii* was found to be present in considerable numbers in raw milks, 3.2 being the average number found to each 20 cc. It was found with practically equal frequency in pasteurized milks, less frequently in inspected milks, and

rarely if ever in certified. It is thought that the presence of this organism, 3 to 4 per cubic centimeter, is an indication of contamination. It is said that a high spore count in a pasteurized milk indicates either a poor raw milk, a low pasteurizing temperature, or contamination with heat-resisting forms after pasteurization. Certified milk and good inspected milk had surprisingly few spore forms.

The rate at which colonies on agar plates incubated at 21° C, develop may be used to differentiate different grades of milk, being more rapid in the raw than in the pasteurized or certified milks.

In a study of the curd produced by milks of the various classes at 37° it was found that raw and pasteurized milks all promptly formed lactic acid curds, while the inspected and certified milks more frequently formed sweet or gaseous curds.

A number of milks were heavily seeded with *Bacillus coli* and then pasteurized at 60° for 20 minutes. By this procedure It was found impossible always to kill all of the *B*, coli present.

Bacteriological inquiry on sterile milk sold in Brussels, H. Kufferath (Ann. Gembloux, 24 (1914), No. 8, pp. 417-424; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Discases, 5 (1914), No. 11, p. 1511).— From his observations the author concludes that the maximum limit for the number of bacteria allowable in sterile milk should be about 50,000 per cubic centimeter, estimated by counts on gelatin plates kept for three days at a temperature of 38° C. At the same time no injurious bacilli such as coli and tuberculosis forms must be allowed.

Relation of the number of Streptococcus lacticus to the amount of acid formed in milk and cream, P. G. Heinemann (Jour. Infect. Diseases, 16 (1915), No. 2, pp. 285–291, fig. 1).—From his study the author concludes that "the amount of acid formed in the souring process of milk or cream is not dependent solely on a definite number of bacteria of the S. lacticus group. Temperature and the presence of other bacteria may influence the result. In raw milk or cream, or in raw milk or cream inoculated with cultures of the S. lacticus, the number of bacteria increases to a given point and then decreases. At 37° C. the maximum is reached after 24 hours and at lower temperature after several days.

"Coagulation of milk or cream is not solely dependent on a definite amount of acid or a definite number of bacteria. This absence of definite relation between coagulation, on the one hand, and acid and number of bacteria, on the other hand, may be due to the kinds of bacteria present, the kind of acid formed, and the activity of the enzyms produced by bacteria. At 37° extraordinarily high amounts of acid may be produced after several days, due probably to the activity of enzyms produced by the 8. lacticus and to the presence of members of the group of lacto bacilli."

Milk poisoning due to a type of Staphylococcus albus occurring in the udder of a healthy cow, M. A. Babber (Philippine Jour. Sci., Sect. B, 9 (1914), No. 6, pp. 515-519).—This is an account of milk poisoning in the Philippine Islands, where acute attacks of gastroenteritis were produced by a toxin elaborated by a white staphylococcus which occurred in almost pure culture in the udder of a cow. The fresh milk was harmless, and the toxin was produced in effective quantities only after the milk had stood some hours at room temperature. Culturally the toxin-producing staphylococcus differed little from a nontoxin-producing strain, except that the former produced acid in mannite and maltose agars.

It is said that "cases of gastroenteritis occurring in the Tropics and in the warm season elsewhere may be due to a toxin of similar origin, especially

where fresh milk is not properly refrigerated before use. This is the more probable since staphylococci of various types commonly occur in the udders of apparently healthy cows."

Premature curdling of milk during a thunderstorm, R. Wernicke (Mitt. Landw. Inst. Leipzig, No. 12 (1914), pp. 97-129).—In tests made of samples of milk taken from five cows during a thunderstorm it was found that in several cases an increase in germ content occurred at the time of the storm, while in other cases it occurred several hours previous to the storm. It was evident that the weather conditions were conducive to bacterial infection.

These observations correspond to the results obtained by Zieschang in contactinfection experlments with milk palls and bottles. These changes were noted,
even though there was no perceptible smell of ozone in the air. The raising of
the air temperature is given as another probable cause for the premature curdling of milk during thunderstorms.

Clarification of milk, B. R. Wright (U. S. Patent, 1,122,457, Dec. 29, 1914; abs. in Jour. Soc. Chem. Indus., 34 (1915), No. 4, p. 196).—" Milk is delivered into the center of a rotating centrifugal drum and passes through narrow passages to a peripheral space where the heavier impurities are deposited. The milk is then returned, in the form of a number of sheet-like streams, through other narrow passages toward the center of the drum and the outlet. Clarification is thus effected without materially changing the distribution of the butter fat globules in the milk."

Cows' milk for infants in Saxony, E. W. Thompson (Daily Cons. and Trade Rpts. [U. S.], 17 (1914), No. 155, pp. 65-68).—This is the original of an article previously noted (E. S. R., 31, p. 573).

Goat's milk and its uses (Food and Drugs, u. ser., 3 (1915), No. 1, pp. 20-24).—This article discusses the characteristics and composition of goat's milk and its value as a food for infants and invalids.

Making whey butter at Cheddar cheese factories, J. L. Sammis (Wisconsin Sta. Bul. 246 (1915), pp. 3-24, figs. 6).—This bulletin describes in detail the source of income, expense, profit, and various practical methods of conducting a whey separating and churning business. It is stated that the quality and value of whey cream are largely determined by the sanitary conditions of milk production and the care given the cream after separating. Whey cream should contain 50 or 60 per cent of fat. It should be skimmed early, cooled quickly, churned promptly with from 75 to 100 per cent of good starter, and kept at a low temperature throughout to insure the best results. Churning is not deemed so profitable as separating whey cream, and therefore the smaller factories usually prefer to sell to a central churning station or to a regular creamery.

Ice cream standards, W. B. BARNEY (*Proc. Assoc. Amer. Dairy. Food and Drug Officials, 18* (1914), pp. 226-233).—The author discusses the feasibility of a fat standard for ice cream, believing that as far as it goes it is very practical, but that alone it is not sufficient. It is stated that the use of fillers and binders should be permitted in the manufacture of ice cream, provided they are of good quality.

Report to the local government board upon the effects of certain condensing and drying processes used in the preservation of milk upon its bacterial contents, S. Delépine (Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Mcd. Subjs., n. ser., No. 97 (1914), pp. 49, pls. 7; abs. in Dairy, 27 (1915), No. 314, p. 44).—In his studies the author found that the total number of bacteria present in mixed cows' milk, such as is usually supplied to town customers, was considerably reduced by the several methods of manufacturing condensed milk. The reduction was greatest in the case of the manufacture of sweetened condensed milk and least in the case of the drying of milk sprayed into a current

of hot air. The drying of milk over heated revolving cylinders occupied an intermediate place.

In each of the three methods of treatment there was a stage at which the reduction in the total number of bacteria was much greater than that observed in the finished article ready for sale. The increase in the number of bacteria observed during the final state is ascribed to recontamination.

"The reduction in the total number of bacteria was almost entirely due to the death of streptococci, staphylococci, sarcine, bacilli of the *Bacillus coli* type, streptothrixes, yeasts, etc.

"At none of the stages of preparation was the milk ever found completely sterile. The amount of heat to which the milk was submitted was insufficient to bring about the death of several saprophytic and of some pathogenic bacteria. Among the saprophytic bacteria which were invariably found to resist pasteurization those most commonly detected were sporing bacilli of the types included under the term *B. mescntericus*. Some streptothrixes appeared in some cases to have survived, but the evidence on that point was not conclusive."

Some living tubercle bacilli of bovine origin were found to have survived treatment of drying milk over heated revolving cylinders, while the drying of milk in a current of hot air had even less effect on tubercle bacilli. These bacilli were capable of producing tuberculosis in guinea pigs, but the course of the disease was much slower than that of the disease produced in guinea pigs inoculated with the same amount of untreated tuberculous milk.

Experiments relating to the creamery and dairy, A. Burn (Ber. Landw. Reichsamte Innern, No. 35 (1914), pp. 227, figs. 7).—This reports experiments on methods of testing milk and cream, and the operation of separators and other creamery equipment.

Report [of] marketing conference held in Chicago, October 29, 1914, at [the] National Dairy Show (Chicago: Drovers Journal Press [1915], pp. 30, pl. 1).—The papers given at this conference, which was held in connection with the Ninth National Dairy Show, were Milk Marketing and City Distribution, by C. F. Whiting (pp. 4-8); The Marketing of Butter, by L. D. H. Weld (pp. 8-18); Ice Cream Marketing, by M. Mortensen (pp. 19-24); and The Transportation of Dairy Products, by E. M. Wentworth (pp. 24-30).

VETERINARY MEDICINE.

Farm animals in health and disease, A. Machens (Die landwirtschaftlichen Haustiere in gesunden und kranken Tagen. Ratisbon: J. Habbel [1914], pp. 371, pls. 11, figs. 139).—A handbook of instruction on hygiene as related to the horse, ox, pig, sheep, goat, and farmyard fowl, the recognition of disease symptoms, first aid in sickness and accident, etc.

Collected papers of the Lister Institute of Preventive Medicine (Lister Inst. Prev. Med., Collected Papers, No. 10 (1913-14), pts. 1, pp. 688, pls. 16, figs. 41; 2, pp. 650, pls. 13, figs. 44).—Part one deals with bacteriological, epidemiological, pathological, and statistical papers, and part two with biochemical, physiological, and zoological papers.

The biology of the blood cells with a glossary of hematological terms, O. C. Gruner (Bristol, England: John Wright and Sons, Ltd., 1913, pp. XII+392, pls. 30, flgs. 37).—This work deals with the subject under the headings of the primordial blood cell, the red blood cell, the lymphocyte, the large mononuclear leucocyte, the neutrophile leucocyte, certain phlogocytes, and the cytoplastic phenomena of blood-forming tissues. References to the literature, a glossary of hematological terms, a general index, and an index of diseases of animals, and authors are included.

Digest of comments on the Pharmacopæia of the United States of America and on the National Formulary, M. G. Motter and M. I. Wilbert (Pub. Health Serv. U. S., Hyg. Lab. Bul. 98 (1914), pp. 518).—This deals with the data acquired from the literature for the calendar year ended December 31, 1913.

Biological products (Pub. Health Rpts. [U. 8.], 30 (1915), No. 4, pp. 256–258).—A list is given of the establishments licensed for the preparation and sale of viruses, sera, toxins, and analogous products. The products which may be sold under the law are mentioned.

The formation of antibodies in rats fed on pure vegetable proteins (Osborne-Mendel stunting food), L. Hektoen (Jour. Infect. Diseases, 15 (1914). No. 2, pp. 279–282, figs. 2).—The purpose of the study was to determine whether or not the formation of antibodies proceeds in the usual way in rats whose growth is arrested by feeding vegetable proteins but in which no disturbance of general health is observed. Two sets of experiments were carried out, each involving a group of stunted and normal rats. Similar results were obtained in each case. "It appears, then, that so far as the results of these experiments indicate, the arrest of growth in rats by the Osborne-Mendel method does not cause any disturbance in the production of antihodies."

Serodiagnosis of pregnancy, E. Abderhalden and A. Fodor (München. Med. Wehnschr., 61 (1914), No. 14, pp. 765-767; abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 20, p. 1591).—Besides the optic and dialysis methods a third method for diagnosing pregnancy has been evolved, viz, the determination of the nitrogen in the dialyzate, the results with which compare favorably with the former two methods. The ferments may be demonstrated by the refractometer, the ultramicroscope, polarization, etc., and possibly by staining.

Diagnosis of pregnancy in horses, cows, and goats by the dialysis method, F. Rehbock (Arch. Wiss. u. Prakt. Tierheilk., 40 (1914), No. 4-5, pp. 324-354).—The diagnosis of pregnancy in the horse, cow, and goat is deemed possible by the Abderhalden method (E. S. R., 31, p. 278); with it pregnancy may be diagnosed 12 to 20 days after conception. When the fetus dies negative results are obtained.

The use of Abderhalden's test for diagnosing pregnancy in animals, Schattke (Ztschr. Veterinärk... 25 (1913), No. 10, pp. 425-431; abs. in Berlin. Tierärztl. Wchnschr., 30 (1914), No. 23, p. 404).—The method was tested with particular reference to its value for diagnosing pregnancy in cows. With 54 cows, all pregnant, the test showed positive every time, and with 54 non-pregnant animals it was negative. The dialysis method is said to be a reliable test, but it can only be conducted in a well-arranged laboratory.

Experience with the Abderhalden serum test for pregnancy, J. ROSEN-BLOOM (*Biochem. Bul., 3* (1914), No. 11-12, pp. 373, 374).—Uniformly successful results were obtained with the method. The author is firmly convinced of its reliability.

On the specificity of placental proteins in skin reactions of the human body, F. H. Falls and F. K. Bartlett (Amer. Jour. Obstet., 70 (1914), No. 6, pp. 910-918; abs. in Jour. Amer. Med. Assoc., 64 (1915), No. 2, p. 176).—A local reaction was obtained with placental protein (E. S. R., 32, p. 579) in non-pregnant and pregnant individuals. "The difference in the reaction, however, is neither great nor constant enough to be of value in the diagnosis of pregnancy. This speaks against the theory that the pregnant woman is specifically sensitized to placental proteins. The lack of a general anaphylactic reaction also speaks against the view that the pregnant woman is in fact a sensitized woman. We realize that the method of preparation of the proteins is open to the objection that our manipulations may have so changed the substrate that the specific

ferments could no longer attack it and break it down. That may be true, and yet other proteins capable of sensitizing and producing anaphylactic shock can be handled in a similar manner and retain their specificity, as shown by Vaughn, Wells, and others."

On the protective value of aqueous extract (Hiss) of leucocytes in acute infections in animals, W. E. YOULAND, JR. (Jour. Med. Research, 31 (1915), No. 3, pp. 367-390).—Leucocytes probably do not contain neutralizing substances within the meaning of immunity. Leucocyte extracts apparently exert their actions upon animal infections only in the border line type of infections and are without curative value in more constant conditions. See also a note by Archibald (E. S. R., 31, p. 377).

The effect of intraspinal injections of serums with and without preservatives, J. Auer (Jour. Amer. Med. Assoc., 62 (1914), No. 23, pp. 1799, 1800).—Experiments were carried out on dogs and monkeys to determine what effects are produced when an antimeningococcic serum containing 0.3 per cent of either tricresol or chloroform is injected subdurally. As control injections, horse serum, without any preservative, and Ringer solutions were employed.

It was found that dogs would tolerate up to 6 cc. and more per kilogram of body weight of 0.3 per cent tricresol without danger, as a rule, provided that an efficient artificial respiration is maintained. Monkeys would tolerate injections of more than 6 cc. per kilogram of body weight without any dangerous effect on spontaneous respiration.

"Tests with serums containing 0.3 per cent chloroform, 0.3 per cent ether, or no preservative at all, showed that they exerted qualitatively the same effects when Injected intraspinally as tricresol serum, but quantitatively the disturbances of respiration and blood pressure were definitely less. Chloroform serum caused in general a smaller effect on the respiration and blood pressure than tricresol serum, but the best results were obtained with 0.3 per cent ether serum and with serum without any preservative, although both still occasionally produced in the dog stoppages of the respiration lasting a minute or two and a considerable lowering of the blood pressure. In the monkey, however, normal serum or ether and chloroform serum produced practically only negligible effects on the respiration and blood pressure. . . .

"It should be emphasized that respiratory failure is the great danger after tricresol injection in the dog, and that it occurs only rarely in the monkey."

Preliminary note on the presence of agglutinins for the Micrococcus melitensis in the milk and blood serum of cows in London, J. C. Kennedy (Jour. Roy. Army Med. Corps, 22 (1914), No. 1, pp. 9-14, flg. 1; abs. in Jour. Compar. Path. and Ther., 27 (1914), No. 2, pp. 185, 186).—Although agglutination was noted in some samples in dilutions of 1:20, there were a few reactions in dilutions of 1:300. M. melitensis could not be isolated from either market milk or milk obtained directly from individual cows. When diluted milk was passed through porcelain filters the property of agglutination was reduced considerably.

Revised rules and regulations for the suppression and eradication of infectious and contagious diseases affecting live stock in the State of Georgia, effective on and after December 1, 1912, P. F. BAHNSEN ([Off. State Vet. Ga.], Bul. 7, Ser. A (1912), pp. 29).—This is a compilation of the rules and regulations promulgated which became effective December 1, 1912.

Foot-and-mouth disease, F. PROESCHER (N. Y. Med. Jour., 101 (1915), No. 8, pp. 351, 352, figs. 5).—The success obtained with methylenazur with certain filterable viruses suggested the application of the method to other unknown filterable viruses. Material obtained from the pustules of two typical cases of foot-and-mouth disease (in Europe) in cattle showed that with the "usual bac-

terial stains, carbolfuchsin, methylene blue, and Gram stain, only a few bacteria and cocci were seen, which are, without doubt, ordinary bacterial contamination. With methylenazur, an enormous number of extremely small cocci in the form of diplococci or diplobacilli, sometimes appearing in short chains, closely packed together, were made visible. The majority of the micro-organisms are just within the limit of microscopic visibility (0.1 micron); the largest form are about 0.2 micron. They are metachromatic violet blue; few are stained deep blue. In places where the organisms appear widely separated, they seem to be surrounded by a small colorless capsule."

The author is not prepared to say whether this organism is identical with the cocci isolated by Siegel (E. S. R., 27, p. 378).

Foot-and-mouth disease and the number of live stock (U. S. Dept. Agr., Farmers' Bul. 651 (1915). pp. 4, 5).—A brief statement as to the extent of the occurrence of foot-and-mouth disease in the United States during the recent outbreak. Less than 0.08 per cent of the total number of cattle in the country had been slaughtered to January 1, 1915, in stamping out the disease, and it is pointed out that "if the plague had been temporized with and had gotten beyond control, the United States would doubtless have had to endure permanently an annual loss of many millions of dollars."

Foot-and-mouth disease, A. D. Melvin and J. R. Mohler (Amer. Jour. Vet. Med., 10 (1915), No. 3, pp. 162-170, 204-206; Hoard's Dairyman, 49 (1915), No. 8, pp. 295, 298-301, 304, figs. 3).—This paper on the outbreak of foot-and-mouth disease in the United States in 1914, its history, distribution, methods of handling it, etc., was delivered before the annual meeting of the United States Livestock Sanitary Association. Up to February 9, 1915, 111,868 animals in 2,245 herds distributed over 223 counties in 20 States and the District of Columbia had been infected.

[Foot-and-mouth disease in] the National Dairy Show cattle, W. R. Spann (Jersey Bul. and Dairy World, 34 (1915), No. 14, pp. 450, 451).—This article considers the effect of foot-and-mouth disease on the animals exhibited at the National Dairy Show, which are the only ones that have been kept in quarantine during the 1914 outbreak instead of being destroyed. Of the 719 head 712 contracted the disease, while the 7 remaining proved immune or had it so slight that it was not noticeable. The disease occurred among these animals in a mild form, none of the 712 succumbing to it, and while the udders of many of the cows were affected only 6 cows of the entire lot lost one or more quarters. About 75 per cent of the calves that were born while the cows were affected died. All the animals have been dipped and otherwise disinfected, and contact experiments with susceptible cattle and swine are being carried on to determine whether it is safe to release them from quarantine.

Tick paralysis, J. L. Todd (Jour. Par., 1 (1914), No. 2, pp. 55-64).—The author describes a number of cases of tick paralysis recorded by physicians in southern British Columbia. This is followed by a report of experiments carried on with the lamb, guinea pig, and puppy.

"Previous publications have proved that a paralysis in children may be associated with the bites of ticks in western North America and in Australia; that a paralysis of sheep has been associated with the bites of ticks in British Columbia and in South Africa; that the ticks associated with these affections are of more than one sort; that Dermacentor venustus has produced paralysis in lambs and in a puppy in experiments made under laboratory conditions; that the paralysis following tick bite is probably an individual and novel condition.

"The paralysis of children is not infrequently accompanied by elevation of temperature and by other constitutional symptoms; it is possible that symptoms resembling those observed in children sometimes may appear in adults who have been bitten by ticks. Under experimental conditions by no means every tick bite produces paralysis in laboratory animals. A weak extract of ticks will not cause paralysis when injected into white rats, even though it possesses definite power to prevent the coagulation of blood."

Is the detection of tubercle bacilli in the blood of value in diagnosis? BAETGE (Deut. Med. Wehnschr., 40 (1914), No. 12, pp. 591-593; abs. in Berlin, Tierärztl. Wehnschr., 30 (1914). No. 18, p. 308).—This investigation, made on man, led to the conclusion that blood examinations made with the object of finding tubercle bacilli were of no value, even with the severe cases where the subjects died a short time thereafter.

Determination of tubercle bacilli in the urine, E. GAUTIER (Jour. Urologie, 5 (1914), No. 2, pp. 161-170; abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 14, p. 1125).—The Ziehl-Neelson technique is regarded as absolutely reliable for detecting tubercle bacilli in the urine, provided the decoloration is done with extreme care with 33 per cent nitric acid and with alcohol.

"The method requires much patience, long centrifuging with plenty of fluid, and the slides must be examined all over. If the first examination gives negative findings, the procedure must be repeated with urine voided a few hours later. If a specimen stained with methylene blue shows red corpuscles, degenerated polynuclears, but no microbes, the search for tubercle bacilli must be resumed with renewed energy."

The findings in 28 cases are briefly summarized.

The incidence and bacteriological characteristics of tuberculous infection in children, A. Eastwood and F. Griffith (Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs.. n. ser., No. 88 (1914), pp. 1-104, pls. 6; abs. in Jour. Compar. Path. and Ther.. 27 (1914). No. 1, pp. 80-83).—The object of this work was to determine the incidence of tuberculous infection in 150 children between the ages of two and ten years dying from various causes.

The results are said to supplement those obtained by the Royal Commission on Tuberculosis (E. S. R., 25, p. 884; 26, pp. 884–886). In 56 cases there was no evidence of tuberculous infection, but in the remaining 94 evidence of infection was found, and in the majority of cases the formation of visible tuberculous lesions from which the bacilli could be recovered in culture was noted. In 16 of these cases, although tuberculous lesions were present, the bacilli were apparently dead. Examples of latent tubercle bacilli in the mesenteric or bronchial lymph glands of children showing tuberculosis in some other parts of the body were noted in 22 cases. In five these were of the bovine type and they were lodged in the mesenteric glands once and in the bronchial glands four times. Bovine bacilli were noted in three cases in apparently healthy parts, once in the bronchial and twice in the mesenteric glands; and the human type of bacilli twice, in one from the cervical, bronchial, and mesenteric glands, and in the other from only the mesenteric glands. Death was due to tuberculosis in 61 cases.

In 16 cases the bacilli present in the lesions could not be classified as to type, but of the 78 cases remaining, 65 were due to the human type and in 52 of these tuberculosis was the cause of death. The bovine type was responsible for the infection of 13 cases, and death followed in nine of them.

It is pointed out that distal lesions without lesions at the portal of entry were exceedingly rare. The uncertainty of conducting feeding experiments with animals and small doses of bacilli is emphasized.

An inquiry, based on a series of autopsies, into the occurrence and distribution of tuberculous infection in children, and its relation to the bovine and the human types of tubercle bacilli respectively, A. S. GRIFFITH (Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n. ser., No. 88 (1914),

pp. 105-166; abs. in Jour. Compar. Path. and Ther., 27 (1914), No. 1, pp. 83-85).—
This work, the second series of investigations, was carried out with a view to ascertaining (1) the frequency of tuberculous infection, latent or manifest, in childhood; (2) the distribution of the disease within the body; and (3) the relative incidence of the bovine and the human types of the tubercle bacillus. The tests employed to distinguish between the human and bovine types of bacilli were the cultural characters shown by growths upon glycerinized media and the virulence for certain species of animals. Attention is drawn to certain important factors in carrying out the virulence tests.

"In all, 91 strains from various sites in the bodies of 35 children were tested; of these strains 21 were obtained direct and 70 through the guinea pig. Seventy-two strains from 28 cases exhibited the cultural characters of the human tubercle bacillus, and 16 strains from 6 cases grew like bovine tubercle bacilli. In every case from which two or more strains were isolated the cultural characters of the strains were identical. In one case, a child aged five years who died from meningitis, both human and bovine bacilli were proved to have been present in the bronchial glands. The cultures in this case were obtained through guinea pigs. . . . None of the bovine strains was isolated from children over four years of age. . . .

"Bacilli of the human type were isolated from 26 diseased children and from two that were apparently healthy. In 16 of the 26 the bronchial glands were most severely affected."

Guinea pigs were inoculated with material from apparently healthy bronchial and mesenteric glands obtained from children showing no macroscopic evidence of tuberculosis and in only two cases were tubercle bacilli found. These were of the human type.

"With regard to the portal of entry the following points may be noted: Of eight cases in which the intestines or mesenteric glands were the seats of the primary lesions, six were caused by bovine bacilli and two by the human type. Of 22 cases in which the primary lesions were intrathoracic the whole were due to human tubercle bacilli. Since there is no recorded instance of a child suffering from primary thoracic tuberculosis caused by the bovine bacillus, and since there are no grounds for assuming that the two types behave differently, it must be held that the evidence tends to prove that in those cases in which primary thoracic tuberculosis caused by the human bacillus exists the path of infection has been the respiratory tract."

Analysis of the reaction to tuberculin, F. Klemperer (Beitr. Klinik Tuberkulose, 30 (1914), No. 3, pp. 433-445, figs. 24; abs. in Jour. Amer. Med. Assoc., 62 (1914), No. 24, p. 1932).—It was found impossible to render nontuberculous animals susceptible to tuberculin by the preliminary injection of tuberculin. Consequently the tuberculin reaction can not be considered a phenomenon of anaphylaxis. Animals with a local tuberculous process lose their susceptibility to tuberculin for a time after the local process is excised. This apparently shows that the tuberculin reaction is not due to antibodies circulating in the blood.

Tracings and tabulated details of the experiments on rabbits and guinea pigs and some clinical data are given.

An aid to prognosis in pulmonary tuberculosis. A simple urinary test: The urochromogen reaction of Weisz, J. Metzger and S. H. Watson (Jour. Amer. Med. Assoc., 62 (1914), No. 24, pp. 1886–1888).—The Weisz urochromogen test was tried on 113 patients. The conclusions drawn are as follows:

"The presence of a urochromogen reaction in the urine of a patient sick with pulmonary tuberculosis is for the time being of unfavorable prognostic import. The persistent presence of a urochromogen reaction in the urine, in spite of proper treatment, probably means a hopeless prognosis. Its absence is generally, though not invariably (regardless of how sick the patient seems), of good prognostic import. Its prompt and continued disappearance soon after treatment is instituted, in a patient who showed it before treatment, so far as our experience goes, is a favorable prognostic sign; but it will take several years' observation of these particular patients to determine this point conclusively.

"Finally, it is not an invariable guide to prognosis, but in the majority of cases is of much value, and as all prognoses must be good, bad, or doubtful, it will, if judicially used, help materially to reduce the number in the doubtful class."

Curative tests against tuberculosis, Velasko (München. Tierürztl. Wehnschr., 65 (1914), No. 11, pp. 248. 249).—A six-year-old ox having typical clinical signs of pulmonary tuberculosis was given two injections of Burow's tuberculosan with the result that the animal in one-half year's time could have been sold to a butcher at a profit. A young cow having the clinical signs of tuberculosis and also giving a positive opthalmic reaction was treated with three doses of Klimmer's antiphymatol. Five months later all signs indicating a pathological condition had vanished.

The destruction of the vitality of Cysticercus bovis by freezing, B. H. Ransom (Jour. Par., 1 (1914), No. 1, pp. 5-9).—Experiments conducted by the author show that if measly beef carcasses are exposed for six days to a temperature not exceeding 15° F. the vitality of the cysticerci will be destroyed; "that some may survive in carcasses exposed for five days to this temperature, though it is doubtful whether they will retain sufficient vitality to develop in the human host; and finally that a considerable proportion may survive in carcasses exposed to a temperature of 15° for four days or less."

Under the new regulations governing the inspection of meat (E. S. R., 32, p. 777), instead of being refrigerated for three weeks as heretofore carcasses retained on account of *C. bovis*, of which there have been more than 40.000 annually, will be held for six days at a temperature not higher than 15° and then released for food. Thus the refrigeration expense will be greatly reduced since only about a third as much cold will have to be produced for each carcass and only about a third as much storage space will be required to take care of the carcasses.

References to the literature are appended.

Division of veterinary science, M. H. REYNOLDS (Minnesota Sta. Rpt. 1914, .pp. 49-55).—The total loss in the State from hog cholera, both direct and indirect, is estimated at not less than \$5.000.000 for the year. The production of serum increased from 25,000 cc. in 1908 to 1.000.000 cc. in 1913.

An investigation of several proprietary hog-cholera cures and preventives showed that Benetol apparently has no immunizing value when given to healthy hogs exposed to infection and has no curative value when administered to hogs in different stages of the disease. When given internally by drench, unless highly diluted, it is irritating to the mucous membranes of the alimentary tract and when injected intramuscularly is followed by extensive abscess formation. In a similar series of experiments Hudson Hog Cholera Remedy gave very unsatisfactory results, and preliminary trials with Hog Cholera Specific were in no way encouraging and were discontinued entirely when analyses showed that the so-called remedy consisted of a small amount of potassium iodid.

The standardization of antihog-cholera serum, T. P. HASLAM and O. M. FRANKLIN (Jour. Infect. Diseases, 15 (1914), No. 2, pp. 257-267, fig. 1).—The object of this investigation was to ascertain if the various sources of error affecting the methods of standardization of antihog-cholera serum may be re-

duced or eliminated. When pigs are inoculated with increasing amounts of serum and virus, a point is reached at which the pigs no longer show more than a transient fever. This disease is regarded as the protective dose of the serum,

Desiccation appeared to have no effect upon the potency of the serum. When the red blood cells were removed from a serum it was definitely more potent than the serum containing the cells. Serum stored in aluminum vessels for 24 hours was not necessarily affected in potency.

A contribution to the shoat typhoid (Ferkeltyphus) problem, H. Weidlich (Amer. Jour. Vet. Med., 9 (1914), Nos. 10, pp. 728-730, 761, 762; 11, pp. 796-798, 837, 838; 12, pp. 870, 871).—A translation from the German of the article previously noted (E. S. R., 32, p. 83).

The present state of knowledge of swine fever with special reference to the available statistics, M. Greenwood, Jr. (Lister Inst. Prev. Med., Collected Papers, No. 10, pt. 1 (1913–14), Paper 12, pp. 69+111).—A statistical study made at the request of the National Pig Breeders' Association to determine the present state of our knowledge regarding the pathological and administrative procedure relative to swine fever, with special reference to the serum treatment in England and abroad. "The report is divided into the following sections: The pathology and bacteriology of swine fever and swine plague; the history of swine fever and swine plague; the statistical history of swine fever in Great Britain; the statistical history of swine fever and swine plague on the Continent; the experimental basis of immunization; the statistical evidence relating to immunization. Certain statistical data on American field experiments are analyzed in an appendix." The principal conclusions drawn are the following:

"There is strong experimental evidence that both serum and simultaneous (serum and virus) inoculations enable treated animals to withstand infective conditions which prove fatal to the large majority of untreated animals. The duration of this power to withstand fatal infection lasts much longer in animals treated by the simultaneous method. There is prima facie evidence that the same conclusions hold in field practice. The statistics upon which the third conclusion rests are incomplete in various ways, and deductions made from them are subject to suspicion owing to possible fallacies or errors. There is no reliable evidence for or against the view that simultaneous inoculation, properly carried out, is liable to convey infection to healthy pigs. Dorset and his colleagues' original experiments suggest that this danger depends upon the success with which the dose of serum counterbalances the dose of virus, and that a vaccinated animal without symptoms of illness is no danger to others."

Sacks as carriers of swine fever, J. F. D. Tutt (Vet. Jour., 70 (1914), No. 472, pp. 513, 514).—"The writer believes that the fact that sacks are fertile agents of propagation of the infection has long been recognized by the general practitioner, who has unfortunately only too small a share in the control of the disease."

Report on the results obtained by the special committee for investigation of infectious anemia of the horse (*Vet. Jour.*, 70 (1914), No. 474, pp. 604–627, figs. 2).—This is the report of a special committee organized by the Japanese Government in July, 1909, for the investigation of infectious anemia of the horse. The appointment was brought about through outbreaks of the disease in several important breeding districts in Hokkaido and in the northeastern part of Hondo, the main island of Japan. The investigation was continued up to March, 1914, during which time more than 1,000 animals, including 980 horses, 1 donkey, 7 calves, 5 goats, 6 sheep, 7 pigs, and a few other small animals were experimented with.

The report considers the history of the appearances and spread of the disease, its pathogenesis, modes of infection, symptomatology, course and prognosis, therapy, immunization, and preventive inoculation and disinfection. A draft of regulations for its prevention is appended. In investigating its appearance and spread among horses in Japan, it was found that very few cases developed in the stable but on pasture it easily spread with astounding rapidity, a great majority or the entire herd succumbing to it. The experiments conducted led to the conclusion that the entrance of the virus into a healthy individual through its alimentary canal can actually take place but that if it takes place in nature it must be a very slow and limited process. They demonstrate that the disease can be transmitted without intercourse between healthy and sick horses when the free access of insects is not prevented.

In pasturing experiments the disease was spread in both May and June when horseflies (Chrysopus japonicus and Hamatopota tristis) appear and in July and August when several species of Tabanus occur, thus leading the committee to conclude that horseflies are the real transmitters of infectious anemia among horses in Japan. It is known that horses become immune to the disease but the results of preventive inoculation experiments thus far have been negative.

The use of artificial sera for strangles in horses, SUSTMANN (Berlin, Tierärztl, Wehnschr., 30 (1914), No. 29, pp. 516, 517).—Good results were obtained in severe and atypical cases by giving subcutaneous injections of artificial sera composed of the following ingredients: (1) (Hayem's) sodium chlorid 5 gm., sodium sulphate 10 gm., boiled water to make 1,000 cc.; (2) sodium chlorid 2½ gm., sodium sulphate 5 gm., sodium nucleinate 2 gm., and boiled water to make 500 cc. Both of these solutions, which are administered at blood heat, should be tried for other diseases.

The pathology of pseudotuberculosis of rodents caused by Bacillus pseudotuberculosis rodentium, T. Messerschmidt and Keller (Ztschr. Hyg. u. Infektionskrank., 77 (1914), No. 2, pp. 289-303).—This work deals briefly with the morphological cultural, and serological characteristics of B. pseudotuberculosis rodentium, its resistance to heat and disinfectants, pathogenicity for experimental animals, etc. Histologic studies are also reported upon.

RURAL ENGINEERING.

Irrigation development in Montana, S. T. Harding (Montana Sta. Bul. 103 (1915), pp. 211-336, figs. 9).—This bulletin was prepared under a cooperative agreement between this Office and the Montana Station. It does not deal with the practice of irrigation, but gives data as to the present and prospective irrigation development of the State based on a study of the available water supply and of the lands so situated as to be capable of irrigation, which are described in eight divisions according to climatic, physical, and agricultural conditions. Considerable statistical and legal data with reference to agriculture and irrigation in the State are given and irrigation projects in the different divisions are described in detail.

It is stated that there is now leaving Montana an average of from 30.000.000 to 35,000,000 acre-feet of water per year. The direct flow without storage would supply, if fully used, about one-third this amount.

Drilling 30-inch wells for irrigation, F. W. PARK (Irrig. Age, 30 (1914), No. 1, pp. 393-395, 415, figs. 5).—It is the main purpose of this article to explain how these large diameter wells are sunk to receive deep-well pumps.

Solving the silt problem, L. C. Hill (Engin. Rec., 70 (1914), No. 23, pp. 609, 610).—The author suggests for muddy streams in the Southwest the construction of reservoirs at the head of the irrigation canal systems to prevent the

filling up of irrigation canals and the choking of headworks. He considers the danger of the silting up of such reservoirs to be negligible.

Water for irrigation and stock, J. C. BRÜNNICH (Queensland Agr. Jour., n. ser., 2 (1914), No. 6, pp. 406-410).—Notes are given on water in general and on the conditions under which waters are suitable for irrigation and stock watering.

Economical duty of pumps, F. H. Carter (Engin. Rec., 70 (1914), No. 23, pp. 618–620, figs. 4).—The author gives an analysis of the cost of pumps and pumping engines and comparisons between special tests and every-day duty. Diagrams are presented showing the estimated cost of steam pumping engines, the economic duty of pumping engines, and means of finding the comparative economy for pumping engines of different duties.

A report on the methods and cost of reclaiming the overflowed lands along the Big Black River, Mississippi, L. A. Jones, W. J. Schlick, and C. E. Ramser (U. S. Dept. Agr. Bul. 181 (1915), pp. 39. pls. 11, figs. 19).—This report is based on a survey of the overflowed lands along the Big Black River, which was finished August 15, 1913. It describes briefly the conditions found, discusses the drainage problems encountered, and presents the plan of drainage considered most practicable.

The area to be improved comprises 133,460 acres of bottom land bordered by rough rolling land and steep hills. The valley has a fall of 3 ft. per mile at the upper end of the district which gradually decreases to $1\frac{1}{2}$ ft. at the lower end. The soil of the Big Black bottoms is very uniform in texture and is composed of a silty loam underlain by clay.

From studies of run-off in watersheds similar to and in the same general locality as the Big Black watershed, the following formula of the Murphy type was deduced upon which the design of all levee improvements was based:

$$Q = \frac{18700}{M + 144} + 18$$

Q=discharge in second-feet from each square mile and M=the watershed area in square miles. For computing the size of all ditches the following formula was deduced:

$$Q = \frac{1000}{M} + 15$$

The general plan as proposed for the drainage of the Big Black River bottoms consists of the construction of a main ditch and of the necessary laterals at the upper end of the valley, the construction of levees, the clearing of a floodway through the bottoms, including the present river channel, and provision for interior drainage by the construction of ditches and the clearing of present channels.

"In computing the sizes of ditches and levees and the capacities of the floodways, the Chezy formula, $v=c\sqrt{rs}$, was used. In this formula c is . . . determined by Kutter's formula, in which the coefficient of roughness, n, was taken at 0.030 for ditches, 0.035 for cleared channels, and 0.040 for floodways. To provide a margin of safety, ditches were given a depth of 1 ft. greater than that computed as necessary to handle the discharge. The tops of the levees were taken at 3 ft. above the high-water line as computed. . . .

"To carry out this work 36 drainage districts are planned, having a total area of 96,088 acres. The estimated cost of this work, exclusive of that of clearing the main floodway, varies in the different drainage districts from \$15.72 to \$44.36 per acre, the average cost per acre for the entire 36 districts being \$23.06."

Tables of run-off data, bench-mark locations, and a number of maps of the proposed Improvements are appended.

Reclamation of the swamp and overflowed lands of North Carolina, J. H. Pratt (N. C. Geol. and Econ. Survey Press Bul. 134 (1914), pp. 6).—In discussing drainage conditions in the State data are given showing that there are 46 districts in the swamp areas and 34 districts in the overflowed areas which will reclaim an aggregate of 942,121 acres. It is stated that thorough drainage pays and is one of the most profitable investments in the State.

Preventing erosion in Piedmont drainage districts (N. C. Geol, and Econ, Surrey Press Bul. 133 (1914), pp. 5).—Brief instructions for preventing erosion are given.

Topographic surveys for drainage districts, J. S. Bowman (*Proc. Iowa Engin. Soc.*, 26 (1914), pp. 96-100).—The author discusses the process of topographic surveying for drainage districts, emphasizing as essential features the completeness of data for the design and its reasonable cost.

Cost of excavating drainage ditches with steam and electric machines (Engin. Rec., 70 (1914), No. 26, pp. 704, 705).—Comparisons are made of dragline and suction dredges operated on the North Side Minidoka Project of the U. S. Reclamation Service, in which work both steam and electric machines were used. "While the latter were much higher in first cost, the operating expense has been so much lower than with steam machines that this handicap has not merely been overcome, but a substantial saving recorded as against the performance of the steam machines." Detailed cost data are given.

Subsoiling demonstration with explosives, D. Turner (Ann. Sci. Bul. Roy. Agr. Col. Circneester, No. 4-5 (1912-13), pp. 79-81).—Subsoiling with explosives in a heavy calcareous loam produced no increase in the crop of potatoes the following season. This result is attributed to the wet condition of the soil during blasting and to the use of too heavy charges of explosive.

Location and construction of highways in mountain country, F. W. Harris (Engin, News, 72 (1914), No. 25, pp. 1199-1201, figs. 5).—This article deals with pioneer road construction and improvement when the problem is to get as many miles of good passable highway as possible for a fixed appropriation, with particular reference to far western conditions. The author argues against the 5 per cent maximum grade and points out many of what he considers to be its fallacies for such highways. The successful use of a drag-line scraper on such works is described.

Bituminous macadam roads in Rhode Island, I. W. Patterson (Municipal Engin., 47 (1914). No. 6, pp. 437-441).—The results obtained with a number of test sections of road laid in 1909 led to the conclusion that "upon the whole, the cold-mixing method of constructing bituminous macadam as practiced in Rhode Island appears to be an economical pavement for motor vehicle traffic. It does not appear to the writer as suitable for heavy horse-drawn traffic or for a heavy mixed traffic."

Standard small culverts recommended by the Illinois Highway Commission (*Engin. and Contract.*, 42 (1914), No. 25. p. 572, figs. 5).—Drawings and tables of quantities for concrete culverts used by the Illinois State Highway Commission are given.

Steel bridge standards of the Iowa Highway Commission, E. F. Kelley (Engin. Rec., 70 (1914), No. 24, pp. 631, 632, figs. 5).—The types of structure adopted by the commission are: I-beam spans with 16, 18, and 20 ft. roadways for spans from 16 to 32 ft., inclusive; pony trusses with 16 and 18 ft. roadways for spans from 35 to 100 ft., inclusive; and through trusses with 16 and 18 ft. roadways for spans from 100 to 150 ft. Expansion is provided by sliding or rocker shoes.

Experiments on road dust prevention, W. A. THAIN (Ann. Sci. Bul. Roy. Agr. Col. Circnester, No. 4-5 (1912-13), pp. 102-104).—Tests of granular cal-

cium chlorid led to the conclusion that it appears to be a particularly suitable, effective, and cheap dust preventive for estate and farm roads.

Ontario highway laws (Toronto: Comv. Highways, 1914, pp. 147).—The text of these laws is given.

Notes on the tests of some large reinforced concrete pipe, W. J. SCHLICK (Iowa Engineer, 15 (1914). No. 3, pp. 103-110, figs. 5).—Tests of the supporting strength of a number of reinforced concrete bell and spigot tile in 8-ft. lengths and with diameters of from 18 in. to 48 in. are reported. The reinforcing in the 36-in. and 48-in. pipe was of \(\frac{3}{2}\)-in. bars spaced 3 in. and 3\(\frac{3}{4}\) in., respectively, with \(\frac{3}{2}\)-in. longitudinal bars to which the circular rings were wired. Triangular mesh reinforcing was used for the other three sizes, No. 4 mesh being used for the 18-in, pipe and No. 23 mesh for the 24-in. and 30-in. sizes.

In the bar reinforced pipes cracking, especially on the sides, was confined to a few main cracks, while in the mesh reinforced pipes the cracking in the sides was much more distributed and regular. In all cases cracking in the top and bottom was confined to a fewer number of cracks than in the sides, and there was apparently no fixed relation between the load at which cracking begins and the maximum load. "All difference in the character and number of cracks seems to be traceable to the amount, kind, and location of the rein-Corrugated reinforcing was no more effective than smooth reinforcing. The elongation of the horizontal diameter of the pipe at the critical load averaged from 0.05 to 0.75 in. "For lateral extension of 0.01 in. to 0.05 in, the ditch filling would not be sufficiently compressed to give any lateral support. . . . It seems evident that some method of anchoring the reinforcing at the top and bottom would have made the steel more effective. The development of the principal side cracks so near to the point where the reinforcing crosses the neutral axis indicates that the reinforcing would have been more efficient had it been so located as to cross the neutral axis of the pipe wall at the 45-degree point. Although no definite turning point was evident during the tests, the data show that the safe load for these pipes was somewhat less than one-half the maximum load."

Farm surveying, R. H. Smith (Farm Engin., 2 (1914), No. 5, pp. 83-85, figs. 5).—This article describes and illustrates the process of leveling with homemade instruments.

Alcohol as fuel, B. O. Jenkins (Sci. Amer., 111 (1914), No. 25, p. 509).—In summarizing the relative positions of the possible sources of cheap industrial alcohol, particularly for use in farm gas engines, it is stated that colonial-grown maize stands first in importance, followed by wood sawdust. "With the present information available, neither potatoes, beets, nor peat appear as favorable as is generally supposed."

Electricity in rural districts, J. L. White (Jour. Electricity, 34 (1915), No. 1, pp. 10, 11).—This article gives suggestions as to the means whereby central stations can increase the use of electric current in rural districts.

Small motor applications for farm work, C. J. Roher (Trans. Amer. Soc. Agr. Engin., 7 (1913), pp. 151-176, figs. 15).—The author deals with the use of electricity on the farm. He points out that electricity is being used for over 125 different farm operations, of which there are 50 in the farm home, 20 in the dairy, and 30 for farm and field machinery.

It is stated that 1 cent's worth of electricity at 10 cts. per kilowatt-hour will operate a 6-lb. flatiron for fifteen minutes, drive an electric vacuum cleaner long enough to clean 450 sq. ft. of carpet, lift 100 gal. of water 100 ft., keep a heating pad hot for from two to three hours, or run a sewing machine two hours, a 12-in. electric fan two hours, or a buffer and grinder 14 hours.

Tests made on an eight-machine milking equipment driven by a 3-horsepower motor indicate that the power cost is about 2 mills per cow with electricity at 10 cts, per kilowatt-hour. The average load on the motor was 2.3 horsepower and the vacuum maintained by the pump was 15 in. A test of a feed grinder running at 650 revolutions per minute and driven by a 5-horsepower motor showed the power consumption when grinding corn to be 0.433 kilowatt-hour per bushel. Tests on another grinder driven by a 15-horsepower motor showed a current consumption of 0.411 kilowatt-hour per bushel.

Results secured with a small thresher having a 28-in, cylinder and a 42-in, separator and driven by a 15-horsepower electric motor showed that the power consumption incident to threshing a ton of oat straw averaged about 2.62, of barley 2.36, and of wheat 2.27 kilowatt-hours. The power consumption per bushel of oats averaged 0.07, of barley 0.108, and of wheat 0.16 kilowatt-hour.

The sizes of motors suggested to be used for different farm operations are given in the following table:

| Machine. | Horsepower of motor. | | | | Horsepower of motor. | | |
|--|---|---|--|--|--|--|--|
| | Mini- mum. | Maxi- mum. | Size most com- monly used. | Machine. | Mini- mum. | Maxi- mum. | Size most com- monly used. |
| Household machines: Sewing machine Buffer and grinder Yacuum cleaner Ice-cream freezer Washing machine Meat grinder Water pump Dairy machines: Water pump Cream separator Churn Mikking machine, vacuum system Refrigeration Farm machines: Feed grinders (small). Feed grinders (large). Silage cutters. Shredders and huskers. Sizes of motors to use on different machines,

Farm experience with the tractor, Λ . P. Yerkes and H. H. Mowry (U. S. $Dept.\ Agr.\ Bul.\ 174\ (1915),\ pp.\ 44)$.—This bulletin reports data based on the experience of a large number of both successful and unsuccessful users of tractors west of the Mississippi River, as well as replies to a circular sent out to bankers in that section.

Attention is called to the fact that the data represent a record of a machine in the process of development and not of a completed and perfected outfit. "Most of these tractors have been operated by men who were not properly trained and equipped to handle them efficiently, and during the first few years of the development of the gas tractor the machines placed on the market were mainly large outfits, which were necessarily expensive, and failure meant a heavy financial loss.

"It is generally recognized that the gas tractor was of great value in rapidly breaking up large areas of prairie sod in the West at a time when horses were not available, but after the sod was broken they proved an unprofitable investment for the individual farmer in a large percentage of cases. A few owners have found the tractor a very profitable investment, doing its work more satisfactorily and much cheaper than could be done with horses, while a great many discontinued its use after a trial. The percentage of owners reporting favorably regarding the tractor decreases with the length of time they have used their outfit, due partly to the fact that the older machines were not as good as the later ones, but mainly to a better realization of the tractor's value in their work. . . . Owners who report unfavorably regarding the tractor obtain poorer average results than those who state that the tractor is a good investment. . . .

"The average life of a tractor as estimated by owners in North Dakota is about six years, while the average life as estimated by owners in States other than North Dakota is about eight years. To judge by the small percentage of reports received for tractors three or more years old, it would appear that a large number of outfits three, four, and five years old are no longer in use, indicating that the average life is even less than six years. The plowing done with tractors has been little, if any, deeper than that done with horses. Combination work is not practiced to a great extent, and usually is limited to harrows or drags after the gang plow. The percentage of tractors which are operated at night is comparatively small, varying from 11 to 14 per cent, although the tractor's efficiency at night is very good. No injurious packing of the soil is caused by the tractor's wheels if the soil is in proper condition to be worked. The item of repairs has been one of considerable importance in connection with the use of farm tractors, but the data indicate that a large percentage of such repairs have been caused by inefficient operation.

"The necessity for the operator of a gas tractor being thoroughly trained for his work, if a tractor is to prove a success, is obvious. . . .

"The tractors which have been operated by kerosene show, as a whole, slightly better average results than those operated by gasoline, indicating that the heavier fuels can be burned at least as satisfactorily as the lighter ones. The amount of kerosene used per unit of work, however, is usually slightly more than for gasoline, which would appear to indicate that the combustion of the kerosene is generally not as perfect as that of the gasoline. This is partly due to the fact that many owners are burning kerosene in tractors equipped with ordinary gasoline carburetors. . . .

"The data apparently show that the tractors with drawbar ratings of 15 horsepower are giving slightly better results than either the larger or smaller sizes. The tractor has not, as a rule, displaced its equivalent in work horses as regards either power or value. Its purchase, therefore, usually increased the investment in power, as well as in certain kinds of equipment. The necessity for a large acreage, if the invested capital per acre is to be kept within a safe limit, is very apparent, although in many farming communities a tractor may prove profitable on a small acreage, provided the owner can obtain some lucrative custom work for the tractor when it is not required on the home farm. . . . The modern gas tractor of 10 or more horsepower has thus far, within its limited area of use, proved to be an auxiliary of the farm horse rather than a substitute. . . .

"Up to the present time the tractor appears to have made for itself no important place in the agricultural economy of this country. In a few limited localities in the West where conditions especially favor its use large tractors are used by some men with apparent profit. The general situation, however, indicates that the large tractor is not to be a factor in increasing farming by extensive methods and on a large scale, for a few years at least. Instead

there are indications that the tractor of the future must make possible more intensive agriculture on farms of moderate size, though the large outfits will probably continue to be used on some of the exceptionally large farms in the West. It is worthy of note that some of the successful users of tractors were able to reduce the number of their farm horses. This fact suggests that there may be a field for farm reorganization to make possible the economical utilization of the tractor."

An efficient alfalfa ditcher, L. M. LAMPSON and B. HUNTER (Washington Sta. Poputar Bul. 81 (1915), pp. 4, figs. 3).—A ditcher for cleaning out the furrows in furrow-irrigated alfalfa is described and illustrated. It consists essentially of a single-shovel plow and a slide drag attached to a wooden tongue. The plow pulls against a 10-in, coil spring on the end of its beam. It is claimed that with this device the furrow can be cleaned out to within 7 ft. of the head ditch on account of the doubletree being hitched behind the plow instead of to the end of the plow beam. It is also claimed that the draft of this ditcher is approximately one-third less than that of the ordinary ditcher and that the weight of the driver upon the slide is sufficient to hold the plow in position.

The trade in agricultural machines in France, G. Coupan (Vic. Agr. et Rurate, 3 (1914), No. 18, pp. 469, 470, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. But. Agr. Intel. and Plant Diseases, 5 (1914), No. 6, pp. 805, 806, fig. 1).— The greatest quantity of agricultural machines and implements imported into France is said to have come from the United States, namely, 55 per cent in 1895 and 69 per cent in 1912. The next most important country in this connection is the United Kingdom, followed by Germany. Mowers, reapers, and binders are the most extensively imported. French machines are exported chiefly to the French colonies and protectorates.

How to erect small concrete farm buildings (Cement Era, 12 (1914), No. 12, pp. 40, 41, figs. 3).—Methods of the construction of small concrete farm buildings without the aid of mechanics are briefly described.

The wooden hoop silo, W. D. Zinn (West Virginia Sta. Circ. 8 (1914), pp. 4, figs. 2).—A brief description of the construction of the wooden hoop silo is given.

The shower-bath system of sheep dipping (Impl. and Mach. Rev., 39 (1914), No. 468, p. 1660; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 5 (1914), No. 6, pp. 809, 810, fig. 1).—This system is described and illustrated. It consists of a shed 40 ft. long by 12 ft. wide, the roof of which is of flat perforated iron sheets. The dip is pumped by a 3-in. centrifugal pump from a tank to the roof and falls through the perforations onto the 200 sheep beneath, the shower lasting about seven minutes. This method, it is stated, is proving entirely satisfactory, enabling four men to dip 1,000 sheep per hour.

A house for sixty hens, W. E. FRUDDEN (Amer. Thresherman, 17 (1914), No. 8, pp. 74, 75, figs. 3).—A house for sixty hens built on the open but closable front plan is described and diagrammatically illustrated.

Air-cooled apple storage houses, W. N. Hutt (North Carolina Sta. Bul. 228 (1914), pp. 3-31, figs. 23).—It is the purpose of this publication to point out the essential features in the construction of air-cooled apple storage houses and to illustrate both in plan and section typical storage houses which exemplify approved methods of construction and of ventilation.

It is stated that the efficiency of any form of fruit storage house depends on the insulating of a chamber with walls of such material and of sufficient thickness that the temperature within will be affected as little as possible by fluctuations of temperature without. Cement concrete is considered to be one of the best materials for the construction of storage houses. It is further pointed out that in the construction of inexpensive but efficient orchard storage houses it is important to take advantage of the insulating qualities of earth and dead air.

Apertures for ventilation and the intake of cool air are considered necessary for air-cooled storage houses, but windows and doors should be reduced to the smallest possible number and size consistent with convenience. It is stated that the exposed side of the house should face the north, where it avoids the direct sun in the daytime and draws in the coldest air at night.

Hygro-thermographic records taken in a storage house of approved construction showed that in comparison with an outside variation of 37° in temperature the storage chamber showed a total variation of only 11°. Similar records taken in another house showed the same uniformity in temperature, which is considered essential to the success of the storage.

As regards the management of an air-cooled apple storage house, it is stated that in preparation for the crop advantage should be taken of every cool night to lower the temperature of the storage chamber as much as possible. The ventilators should be opened after sundown and the whole house closed tightly before sunup, so as to keep out the warm air. The fruit should be allowed first to cool overnight and then be placed in the storage before sunup. As the weather becomes cooler advantage should be taken of it to lower the temperature and cool down the fruit as much as possible. When all the fruit is in, the house should be opened as little as possible and the fruit left wholly undisturbed.

It is stated that the general consensus of opinion among practical coldstorage men indicates that apples should be stored at a temperature of 30 to 40° F, and pears 33 to 36°.

[Construction of creameries and cheese factories], E. H. FARRINGTON and G. H. Benkendorf (Wisconsin Sta. Bul. 244 (1915), pp. 20-52, figs. 16).—This deals with the location and general features in the construction and arrangement of creameries and cheese factories and illustrates and discusses six different creamery plans which are considered to exemplify good practice. An inspection score card is included.

The disposal of creamery sewage, E. H. Farrington and G. J. Davis, Jr. (Wisconsin Sta. Bul. 245 (1915), pp. 20, figs. 9).—It is the purpose of this bulletin to describe and illustrate suitable arrangements for the purification and disposal of creamery sewage.

It is stated that creamery sowage is not so quickly purified as city sewage owing to the fact that the curd, oil, and sour milk decompose slowly and the lactic acid from sour milk has a tendency to suppress the growth of purifying bacteria and thus retard the liquefaction and gasification of the solid matter. For this reason where a sedimentation tank is used the waste acid from testing milk and cream should not be allowed to run into the drain. Clean water used for cooling purposes should also be excluded.

The septic tank, it is stated, should be large enough to hold at least three days' sewage. "The flow may be estimated (1) by assuming that the amount of sewage from a creamery will be from 1 to $1\frac{1}{2}$ gal, for every pound of butter made, or (2) by calculating the amount of water pumped per day or by measuring the capacity of the supply tank and deducting from the total water pumped the amount used for cooling purposes and not allowed to run into the floor drain."

Some of the special features to be observed in the construction of a septic tank suitable for the digestion of creamery sewage are given as follows: "The cover should be provided with a manhole so that occasionally the sludge at the bottom of the tank may be removed. A grease trap may be placed in the drain between the factory and the tank for the purpose of collecting machine oil and

large lumps of suspended curd. . . . The inlet to the tank should consist of a 6-in, pipe ending in a tee supported by $1\frac{1}{2}$ -in, gas pipes set in the concrete wall of the tank so that the inlet will be submerged. A wooden baffle placed across the end of the tank and extending about 2 ft, below the surface of the sewage will distribute the flow across the tank and will reduce to a minimum the disturbance due to the entering water. At the outlet end of the tank the discharge takes place in a thin sheet flowing over a weir, which may be made of angle iron set on the top of the concrete wall. . . . A wooden baffle similar to the one at the inlet end should be placed about 6 in, from the weir wall to prevent the scum from passing over or clogging the weir. Preferably the tank should be divided into two or three compartments by baffle walls perforated with a number of holes, so arranged as to distribute the flow uniformly throughout the cross section of the tank."

Openings are provided in the baffle walls by placing a number of drain tiles through the forms. "To prevent scum from going through, the upper row of openings should be 18 in, below the surface and to be above the level of the sludge the lower row should be about 2 ft. above the bottom. The walls should have an opening under them near the center for the purpose of flushing the sludge to the sludge drain."

The depth of the tank, it is stated, should be great enough to provide for a considerable depth of scum and sludge and still leave room for the passage of the wastes at a very slow rate, which will require a depth of from 4 to 7 ft, below the level of the water surface. The dimensions of the tank should be so proportioned as to make the length two to three times the width.

A filter bed should be provided for final treatment of the sewage after it comes from the tank. The depth of filter should not be less than 30 in. and preferably from 36 to 48 in., and the area should be such that the rate of application of the settled wastes will not exceed 25,000 gal. per acre in twenty-four hours. A dosing chamber fitted with an automatic siphon for intermittent discharge is considered an essential part of the septic tank.

A two-story sedimentation tank of the lmhoff type in which the solid matter in the sewage drops through slots in the floor of the sedimentation chamber into the lower compartment is described and illustrated as being a suitable device for the digestion of creamery sewage.

For the suppression of odors from the filters the addition of chlorid of lime to the tank effluent about an hour before it is discharged from the dosing chamber is recommended. The necessary amount will vary with the seasons, but it is stated that from 1 to 5 lbs. of chlorid of lime to 1.000 gal. of tank effluent will ordinarily be sufficient.

Design of two residential sewage treatment plants, including settling tanks of Imhoff type, S. A. Greeley (Engin. and Contract., 42 (1914), No. 25, pp. 565-567, figs. 5).—One of these plants, designed for twenty-five people, consists of a settling tank, covered sprinkling filter, and a small secondary settling basin. A tipping bucket drops the dose onto a splash plate, thence to the filter. The second plant consists of a settling tank and a subsurface irrigation system in sandy soil.

RURAL ECONOMICS.

[Needs of American farm women] (U. S. Dept. Agr. Rpts., 1915, Nos. 103, pp. 100; 104, pp. 100; 105, pp. 88; 106, pp. 100).—These four reports consist mainly of extracts from about 2,000 letters received from farm women in response to an inquiry from the Secretary of Agriculture as to how this department could better meet the needs of the farm housewives.

Report 103 relates to the social and labor needs of farm women. The extracts point out some causes of dissatisfaction and contentment among farm women, the function of women's clubs, social centers, amusement, recreation, and the church in improving social conditions, the long hours and overwork, the difficulty in getting domestic help, and cooperative plans for meeting the farm woman's household needs. The abstracts also indicate the effect of the various means of communication upon rural life.

Report 104 includes abstracts relating to the plan, equipment, and management of the farm homes. The principal items mentioned are the house, the garden, labor-saving devices, heating, lighting, sanitation, clothing, preparing and preserving of food, insect pests, and woman's part in the dairy and poultry industries.

Report 105 relates to the educational needs of farm women. They consider that the education of their children can be improved through better schools, cheaper books, transportation of school children, less child labor on the farm, courses in agriculture and domestic science, and boys' and girls' clubs. The farm housewives consider that their condition could be improved through home demonstration agents, libraries and reading courses, meetings and lectures, farm women's institutes, mothers' clubs, school centers, and through special publications and bulletins relating to the problems of the farm women.

Report 106 relates to the economic needs of farm women and points out man's social and labor duty to the women on the farm, the desire for financial recognition of woman's work, and suggests gainful handicrafts and home industries for farm women. Extracts of a more general nature are included relating to farm loans, rural credit, farm prices, marketing, and methods of distribution.

There is an appendix attached to each of the above reports, giving general suggestions for the development of farm women, and indicating how farm women may obtain help under the Smith-Lever Extension Act, and through other branches of the Government. An extensive list of government publications of interest to farm women is included.

Economic history of the United States, E. L. BOGART (New York: Longmans, Green & Co., 1914, 2. ed., pp. XV+597, pls. 7, figs. 115).—This book outlines the economic development of the United States, devoting a large part of its discussions to agriculture. It also contains an extensive bibliography.

York State rural problems, II, L. H. Bailey (Albany: J. B. Lyon Co., 1915, pp. VI+7-262).—This book, supplementing that previously noted (E. S. R., 30, p. 491), is made up of 25 lectures or summaries of lectures, delivered by the author at different places and on different topics, but all dealing with rural problems.

[Problems of production in agriculture], A. D. Hall (Nature [London], 94 (1914), No. 2345, pp. 156-162; 94 (1915), No. 2361, pp. 601-607).—The author outlines various means whereby the world's food supply may be augmented, among them increasing the cultivated area, conserving the water supply as by dry-land farming, irrigation, draining and improving moor land, properly applying fertilizers, increasing the efficiency of agricultural workers, and arranging for the successful employment of research workers.

Ownership, tenure, and taxation of land, T. P. WHITTAKER (London: Mac-Millan & Co., Ltd., 1914, pp. XXX+574, fig. 1).—This book treats of all land whether used for agricultural or nonagricultural purposes. It traces the origin of private ownership of land, the establishment of inclosures, and the lease-hold systems, and shows some of the relationships between agricultural wages and the problems of land tenure and of housing in country and town.

Land revenue, administration, and tenures in British India, F. NOYCE (Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 5 (1914), Nos. 11,

pp. 125-140; 12, pp. 85-98).—This article outlines for British India the tenure of land relative to the States, the relations of the tenants to the landlords, and the administration of the land revenue, by showing its historical development from a system of paying taxes by taking a portion of the cultivator's grain heap to an actual cash payment based upon an estimated value of the land. The article also describes the method of surveying the land and determining its value.

Cooperation in agriculture, marketing, and rural credit, C. B. Austin and G. S. Wehrwein (Bul. Univ. Tex., No. 355 (1914), pp. 100).—This bulletin cites a number of typical instances of cooperation among farmers which illustrates the causes of both failure and success. It describes briefly a number of typical farm organizations and how to form cooperative credit unions under the Texas law.

Rural credits, M. T. Herrick and R. Ingalls (Vew York: D. Appleton & Co., 1914, pp. XIX+519).—The authors have given a historical description of the various types of agricultural credit found in the different countries of the world. In addition, there are chapters on credit, its forms and use, special privilege and state aid, long-term loans and amortization, debentures, principles of land credit and their application, cooperative credit, and the principles of cooperative credit and their application.

How farmers may improve their personal credit, C. W. Thompson (U. S. Dept. Agr., Farmers' Bul. 654 (1915), pp. 14).—In this publication have been considered two general methods whereby farmers may improve their personal credit: That of temporary agreements with existing loan agencies, the agreements terminating with the payment of the loans, and that of permanent articles of agreement among the farmers themselves, or "cooperative credit associations." Three different plans are presented by which the farmers may improve their personal credit with local banks.

Under plan 1, farmers enter into an agreement with local bankers or with other persons who supply the loans to adopt a uniform and approved system of dairy improvement. Those furnishing the funds buy dairy stock, which is sold to the farmers at actual cost plus a certain percentage to cover incidental expenses. The lender takes in payment the farmer's personal note, with or without indorsement, or with mortgage security on the stock purchased. Under plan 2, some additional security is supplied by having the farmers collectively assume a guaranty for the notes given by the members under an agreement. Under plan 3, in place of the limited guaranty supplied by the farmers themselves jointly, as described under plan No. 2, a similar guaranty from a third party is substituted, consisting of local business men who realize their common interest with the farmers in the general improvement of the agricultural conditions in their territory. These men subscribe a certain percentage of the funds loaned, with the understanding that the money is to be a guaranty fund to protect the bankers.

A cooperative credit association has the collective security available under plan 2, and is available continuously for such purposes as may be approved by the association. This publication outlines how such associations are organized and managed and help their members in making the loans productive.

Cotton crop mortgage credit, R. L. Bennett (Agr. and Mech. Col. Tex. Ext. Bul. E. S. 4. pp. 16).—This bulletin outlines a system for conducting a 40-acre farm on the all-cotton basis and on the basis of food, feed. and cotton. The author advocates the changing of the system of farming to one based on food and feed for the farm and all the cotton the individual farmer can then grow.

Farm credit in Wisconsin, B. H. Hibbard and F. Robotka (Wisconsin Sta. Bul. 247 (1915), pp. 66, figs. 12).—This report is based upon a field study of

agricultural credit in Dane and Rusk counties and a part of Douglas County, Wis. The county records of mortgages, statements of local trust and loan companies, bankers, merchants, and farmers were used principally as a source of information.

The report indicates that it was more difficult to obtain loans and that the interest rate was higher in the northern counties than in Dane County, that the mortgaged farms are smaller than the unmortgaged farms but have more live stock and more invested in buildings, and that the average mortgage runs for about five years. Rusk County mortgages are smaller, relatively more numerous, and pay interest at a higher rate than those in Dane County.

The local men furnish nearly three-fourths of the money for Dane County farm loans. Of the Dane County mortgages, 81 per cent are for the purchase of land as compared with 68 per cent of those in Rusk and Douglas counties. Chattel mortgages are more numerous in Rusk and Douglas counties than in Dane County.

It is estimated that store credit interest is 15 per cent per annum and the average account runs for four months.

The report concludes that personal credit is more imperatively needed than land credit, and that this need is more acute in the northern than in the southern counties. A law providing for farmers' credit unions is also needed. Amortization schedules and tables, prepared by E. B. Skinner, are also included.

The Jewish Agricultural and Industrial Aid Society (Jewish Agr. and Indus. Aid Soc. Ann. Rpt. 1914, pp. 67).—This report continues that previously noted (E. S. R., 30, p. 693).

Among the data shown are that 41 per cent of the loans granted during the year were to purchase equipment, 26 per cent to pay off mortgages or other debts, 18 per cent to construct or to repair buildings, 12 per cent to purchase farms, and 3 per cent to increase the working capital. The report also indicated that 29 per cent of the loans were to farmers who had been on their farms less than one year and 20 per cent to those who had been on their farms from one to two years.

[Societies for agricultural production and distribution] (Bd. Trade [Gt. Brit.], Abs. Labor Statis. United Kingdom, 17 (1915), pp. 247-254).—These pages contain statistical tables showing for the societies organized for the production and distribution of agricultural products in the United Kingdom the number of organizations, membership, capital, and business conducted from 1898 to 1912.

[The organization of creameries and cheese factories], E. II. Farrington and G. H. Benkendorf (Wisconsin Sta. Bul. 244 (1915), pp. 3-20).—The authors believe that to insure success there should be at least 400 cows for a creamery and 200 cows for a cheese factory. They point out the distinction between proprietary and cooperative factories and joint stock companies and cooperative associations. There is outlined a method of organizing, articles of incorporation, suggested by-laws, and a scheme for financing the work.

Farm records and accounts, E. L. Currier (Montana Sta. Circ. 43 (1915), pp. 87-109, figs. 2).—The author outlines what he considers the salient features of farm records and how they should be kept. He believes that the farmers should make a daily work record, keep account of all cash transactions, and make an annual farm inventory. He submits model forms and points out some of the most common difficulties in farm accounting and how they may be overcome.

The agricultural outlook (U. S. Dept. Agr., Farmers' Bul. 651 (1915), pp. 1-4, 5-29).—This number gives the estimated number of live stock on January 1,

1915, and indicates that their number for every class has increased during the last year, although the number of cattle, hogs, and sheep marketed at seven of the largest markets shows a decrease.

A prediction by G. A. Bell is given that the big demand for horses will probably occur after peace has been declared. At present the demand is primarily for mediocre animals, but when the war is over the demand will be for high-class animals for use as well as for breeding purposes.

It is estimated that the stock of potatoes on hand January 1, 1915, was 166,846,000 bu., which is a quantity larger than that reported during the last six years. The increased acreage of fall-sown wheat and oats in the cotton States amounted to 3,700,000 acres, or ten per cent of the total cotton acreage.

Apple cold storage holdings are discussed by C. W. Moomaw. Data are given as to the production of upland long-staple cotton. Statistical tables are shown giving estimated total value of 13 crops for 1914, the number of live stock, their total value and value per head and prices of farm products by States on January 1, 1915, with comparative data for earlier years.

Thirty-second annual report of the chamber of commerce. Minneapolis, Minnesota, 1914 (Ann. Rpt. Chamber Com. Minneapolis, 32 (1914), pp. 204).—This report shows for Minneapolis, by statistical tables, the monthly and yearly receipts, shipments, and closing prices for grain, flax, mill products, and hay. It also shows comparative data for other cities, together with their elevator and milling capacity and visible supply.

Report of the Board of Grain Commissioners for Canada (*Rpt. Bd. Grain Comms. Canada*, 1914, pp. 160).—This report discusses the work of the Commission during the year under the topics of inspection and weighing department, the public, and country, lake terminal, interior, and "hospital" elevators, and points out the various difficulties encountered and suggestions for improvement.

Monographs relating to conditions in rural parishes of Portugal (Bol. Dir. Geral Agr. [Portugal], 11 (1912), Nos. 2, pp. 135, figs. 20; 5, pp. 72; 6, pp. 118, figs. 26; 7, pp. 61, figs. 2; 8, pp. 98, figs. 13).—These monographs contain an extensive description of the topography, climate, rural and urban population, agriculture, industries, and commerce of a number of rural parishes of Portugal.

[Agriculture in Egypt] (Ann. Statis. Egypte, 5 (1913), pp. 407-437).—This portion of the annual statistics shows the number of proprietors possessing farms of specified areas and the area in the principal crops and devoted to different agricultural purposes for 1912-13, with comparative data for earlier years. The data are shown for Egypt as a whole and for the major subdivisions.

[Agriculture in Madagascar] (Ann. Gén. Madagascar et Dépend., 1914, pp. 591-608).—These pages give information concerning the development of the crops, forests, and live stock in Madagascar, and describe the problems of their production and distribution.

[Agriculture in Java and Madura] (Jaarc. Konink. Nederlanden, Koloniën, 1912, pp. 60-70).—This portion of the annual report gives the total area in cultivation and the production of the principal crops. The data are given by nativity of the operator and for a series of years.

[Agriculture in Japan] (Japan Year Book, 1914, pp. 337–357).—These pages of the yearbook contain detailed statements regarding arable land, farming population, tenant farmers, farm products, live stock, and special crops. The text is amplified by a large number of statistical tables.

[Expenditure for living in urban and country districts in Australia], G. H. Knies (Commonwealth Bur. Census and Statis. Aust., Labor and Indus. Branch Rpt. 4 (1913), pp. 32-34).—Although the cost of living was practically the same

in both districts, the amounts spent under the different items varied widely. For the urban districts 17.17 per cent of the total was spent for housing, 38.02 for food, 12.90 for clothing, 4.49 for fuel and light, and 27.42 for other items, The distribution for country districts was 8.50, 43.51, 14.32, 4.59, and 29.08 per cent, respectively.

AGRICULTURAL EDUCATION.

Progress of agricultural education in 1912–13, F. B. Jenks and C. H. Lane (Rpt. Comr. Education [U. 8.] 1913, I. pp. 211–233).—This is a review for 1912–13 of the leading features of progress in agricultural education in this country and abroad, including the principal items of interest concerning the agricultural colleges and normal, secondary, and elementary schools in the United States in which agriculture is taught, educational work of the Graduate School of Agriculture, the U. S. Department of Agriculture, the Association of American Agricultural Colleges and Experiment Stations, the American Association for the Advancement of Agricultural Teaching, the Department of Superintendence of the National Education Association, the Conference for Education in the South, and of other conventions, and the principal developments in agricultural education in other lands.

[Contributions to the history of the New York State College of Agriculture] (Cornell Countryman, 12 (1914), No. 3, pp. 167-258, figs. 40).—This number contains the following historical articles: The Relation of Ezra Cornell to the College of Agriculture, by A. D. White; Pioneer Days in Agriculture, by I. P. Roberts; The Later Financial and Physical Development of the College of Agriculture by L. H. Bailey; The New York State College of Agriculture in Its Relation to Agricultural Progress in the United States, by A. C. True; The Development of the Faculty, by A. J. Lamoureux; The Development of the Experiment Station, by J. H. Comstock; The Development of the Conrses of Instruction, by G. N. Lauman; Development of the Graduate Work, by W. A. Riley; The Development of the Land and the College Farms, by J. L. Stone; The Extension Work at the College, C. H. Tuck; Home Economics in the College of Agriculture, by Martha Van Rensselaer; Reminiscences of Early Cornell Days, by W. R. Lazenby; and Some Cornell Boys I have Known, by B. T. Galloway.

Record of the alumni of the Kansas State Agricultural College (Manhattan: Kans. State Agr. Col., 1914, pp. 308, figs. 28).—In addition to the alumni record a history is given of the administrations of five of the presidents of the college and of the present one to date, the courses of study, changes in college life, and attendance.

A preliminary outline of the courses of study in agriculture and minimum of required equipment for the farm-life schools of North Carolina, E. A. Hodson (Raleigh, N. C.: State Supt. Pub. Instr., 1914, pp. 18).—This bulletin also contains suggested additional equipment, text and reference books, and lists of publication for the library.

Division of agricultural extension, A. D. Wilson (Minnesota Sta. Rpt., 1914, pp. 59-68).—This is the annual progress report on the work of the division of agricultural extension, comprising farmers' institutes and clubs, special trains, rural school work, county agricultural agents, short courses, demonstration farms, county fairs, special meetings, publications, aid to cow-testing and live-stock shipping associations, and the production of the "Back to the Farm" play.

The Oka Agricultural Institute, J. M. Liguori (Agr. Gaz. Canada, 1 (1914), No. 11, pp. 907-912, figs. 6).—A description is given of the equipment, courses of study, and staff of the Oka Agricultural Institute at La Trappe, Quebec. This

institute, which is nearly 30 years old, has been recently converted into a scientific agricultural institute, affiliated with Laval University, and now grants the B. S. A. degree. It possesses nearly 2,000 acres of land, half of which is untilled.

Report of the schools' division of the experimental union, S. B. McCready (Ann. Rpt. Ontario Agr. and Expt. Union, 35 (1913), pp. 53-58).—The director of elementary agricultural education of Ontario reviews the origin and aims of the schools' division, discusses its relation to the rural problem and the weakness of the rural schools, and gives an account of the 1913 distribution of plant material to about 400 schools.

School gardens (Agr. Gaz. Canada, 1 (1914), No. 10, pp. 823-832, figs. 4).—Brief accounts are given of the present status of school garden instruction in the Provinces of Nova Scotia, New Brunswick, Quebec, Ontario, Saskatchewan, and Alberta.

The third continuation course in forestry at Heidelberg (Forstw. Centbl., n. ser., 36 (1914), Nos. 8-9, pp. 468-478; 10, pp. 520-530).—A detailed description of the course is given.

The General Education Board, 1902–1914 (New York: Gen. Ed. Bd., 1915, pp. XV+240, pls. 32, figs. 31).—This is an account of the activities of the General Education Board from its foundation in 1902 to June 30, 1914, including farm demonstrations and boys' and girls' agricultural clubs.

Agricultural teaching (U. S. Bur. Ed. Bul. 601 (1914), pp. 87).—This bulletin contains the papers presented at the fourth annual meeting of the American Association for the Advancement of Agricultural Teaching in 1913, and for the most part previously noted (E. S. R., 30, p. 98) or abstracted elsewhere in this issue. Appendixes contain data on summer practicum work at the Northwest School of Agriculture, Crookston, Minn., the use of land by high schools teaching agriculture, the cooperative use of equipment and illustrative material in teaching agriculture, and incomes of pupils from farm work during attendance at school in 1913 in Massachusetts.

Use of land by high schools teaching agriculture, R. W. STIMSON $\pm U$, S. Bur. Ed. Bul. 601 (1914), pp. 50–62).—This paper is a part of the report for 1913 of the committee on the use of land in connection with agricultural teaching of the American Association for the Advancement of Agricultural Teaching.

Replies to a questionnaire sent to high-school teachers of agriculture indicate that in 1913-63 high schools in 35 States reported the use of land at their schools, chiefly for demonstration purposes. The size of experimental or demonstration plats varied from one one-hundred-and-twentieth of an acre to 10 acres. Fifty high schools reported agricultural production on home farm land or on other land apart from the school premises, with more or less attention paid by the agricultural instructors to the home enterprises of their pupils. Replies from individual schools are given, illustrating the differences of opinion as to what should be the scale of operations on school land and what may be done with land by high schools, and illustrating the correlation of class-room instruction with home work and systematic supervision. In conclusion the committee strongly favors the utmost utilization of the home land of the pupils, the closest possible correlation of agricultural class-room instruction with home farm activities, and suitable provision for systematic and efficient supervision throughout the producing season.

The use of land in connection with agricultural teaching in elementary schools, L. S. Ivins (U. S. Bur. Ed. Bul. 601 (1914), pp. 62-76).—This paper, also a part of the committee report referred to above, is based on replies to a questionnaire. The author gives replies describing the work in the 33 States, the District of Columbia, and Porto Rico, reporting the use of land at or near

one or more of their schools, at the home of the pupil, or in connection with regular school work. It is recommended that there be better supervision over home plat work, that land used at or near the school be for demonstration purposes rather than for experiments, that in training teachers of agriculture or school gardening more attention be given to instruction in the use of land, that simple records of work be kept where land is cultivated, and that if land is used by schools having all the grades, the pupils of the upper grammar grades cooperate with the high school pupils in the elementary demonstration projects. Home gardens and vacant lot gardens are deemed more popular than school gardens if they are under similar management and supervision.

Agricultural education for teachers, G. A. BRICKER (New York, Cincinnati, and Chicago: American Book Co., 1914, pp. 172, pls. 4).—This book, which may be considered a handbook for the teacher and a guidebook for the district and the county supervisor and the supervisor of rural or agricultural education, discusses the rise of popular education in agriculture, the problem of intensive agriculture, a popular scientific agriculture, the qualifications and preparation of the teacher of agriculture, agencies for the preparation of teachers, elementary agriculture and nature study, what is elementary agriculture, agriculture as a means of education, pedagogical problems involved in the teaching of elementary agriculture, the administration and teaching of school agriculture, cooperative use of apparatus, equipment, and illustrative material, agricultural demonstration field and home projects, and boys' and girls' agricultural clubs.

Courses in agriculture for the secondary schools of Texas, W. F. Doughty, M. L. Hayes, and W. S. Taylor (Joint Bul. State Dept. Ed., Univ. Texas, and Agr. and Mech. Col. Tex., No. 1 (1914), pp. 166).—In this bulletin the authors offer general recommendations and suggestions on the qualifications of teachers, equipment and state aid, adaptation of courses in agriculture to local conditions as regards scope of courses for schools offering, respectively, one, two, three, and four years' work in agriculture, and agricultural curricula for high schools; on textbooks, notebooks, collections, exhibits, etc., visits and field trips, project work, school-farm and community and extension work; and outlines of syllabi in plant propagation, vegetable gardening, animal husbandry, dairying, poultry raising, soils and soil fertility, field crops, fruit production, farm mechanics, farm management and home grounds, landscape gardening, entomology, and weeds, together with practice work and reference material. A list of the minimum laboratory and agricultural equipment for 12 students is given, and an appendix contains score cards for field crops, farm animals, dairies, butter, and farms.

Course of study in agriculture and domestic science for rural schools (Bul. Nebr. School Agr., Curtis, 1. ser., No. 4 (1914), pp. 32).—This bulletin offers suggestions to teachers as to seed corn, milk testing, a comparative type study of beef and dairy cows, and cooking and sewing.

[Agricultural and home economics instruction in the public schools of New Hampshire], G. H. WHITCHER (N. H. Dept. Pub. Instr., Inst. Circ. 1913–14, Nos. 5, pp. 8; 10, pp. 8; 14, pp. 22; 16, pp. 7; 17, pp. 14; 18, pp. 10; 19, pp. 8; 1914–15, Nos. 1, pp. 7; 5, pp. 14; 6, pp. 6; 7, pp. 13).—These circulars include a discussion of cooking as a means and end in education, and instruction outlines in stock feeding, home-mixed fertilizers, school and home gardening for grade pupils, garden projects in high schools, insects that destroy farm crops, ten serious plant diseases, domestic arts and household appliances, horticulture in the high school, fruit-tree raising, and field work in soil study.

Helps for domestic science work in seventh and eighth grades, November-December (Dept. Pub. Instr. [Ind.], Ed. Pubs., Bul. 13 (1914), pp. 22).—This

bulletin contains definite lessons in cooking and the study of foods and in sewing and the study of clothing for each week in November and December.

Fundamentals of physics, chemistry, and bacteriology in agriculture, F. W. Miller (Columbus, Ohio: Dept. Pub. Instr., 1914, pp. 48, figs. 17).—In this elementary work the author aims to develop and describe the most essential principles of these sciences as preliminary to a course in agriculture, especially in the high school.

Principles and practice of plant propagation, W. L. Howard (Columbia, Mo.: Univ. Mo., 1914, pp. 92).—These discussions and lessons are given in the classes in plant propagation in the University of Missouri and have been developed gradually since 1902. The lectures are intended to cover 15 or 16 1-hour periods or 1-2 year and the laboratory exercises one 2-hour period weekly for 15 or 16 weeks, or one semester.

Program of County Organization Day for boys' corn club, L. N. Duncan and I. B. Kerlin (Alabama Col. Sto. Circ. 30 (1914), pp. 119-122).—This is an outline of a program for the observation of Organization Day and of a suggested constitution, by-laws, and rules for a county corn club.

Elementary flora of the Northwest, T. C. Frye and G. B. Rigg (New York: American Book Co., 1914, pp. 256).—This book was written for the schools of the Northwest and geographically covers Oregon, Idaho, Washington, and the coastal region of southwestern British Columbia. Most of the distinguishing characteristics of the plants are given in the keys, which are complete so far as they go, thus enabling teachers to hand out for analysis plants they do not themselves know.

The story of a kernel of corn, A. W. Nolan (Nature-Study Rev., 10 (1914), No. 8, pp. 307-314, figs. 6).—The life history of a kernel of corn is described.

An industrial study of cotton in the eighth grade, B. Gist (Atlantic Ed. Jour., 10 (1914), No. 4, pp. 13-15).—The author presents statistics of cotton production and consumption by countries, references to literature on cotton, teacher's outlines, arithmetical and other problems on cotton, and correlated spelling.

Seed collections, Anna B. Comstock (Nature-Study Rev., 10 (1914), No. 8, pp. 292-294, fig. 1).—An outline is given for the study of weed seeds.

Rope and its uses, A. A. Burger (lowa State Col. Agr. Ext. Bul. 24 (1914), pp. 48, figs. 196).—This bulletin contains general information on rope and its care and directions for making knots, hitches, splices, halters, and tackles.

Preparation of teachers for nature-study and civic biology, C. F. Hodge (Nature-Study Rev., 10 (1914), No. 8, pp. 294-307).—The author points out the necessity of the adequate reorganization and equipment of normal schools with laboratory, greenhouse, and garden facilities, and of helping teachers already in the work through educational journals, state nature-study and biology leaflets, and practical and inspiring lectures in institutes and summer schools. "Nature-study and civic biology should be the corner stone of national vigor and health conservation."

Birds and nature-study, G. H. Traffon (Bloomington, Ill.: J. G. Coulter [1914]. pp. 16).—This pamphlet for the use of teachers gives a list of references to literature helpful in bird study and suggests work for the children in the schoolroom and out of doors, field work for both the teacher and children, type studies of birds in primary, intermediate, and grammar grades, and an outline and problems for bird study arranged by grades and seasons.

Directions for field studies in agricultural nature-study, G. H. TRAFTON Mankato, Minn.: State Normal School [1914], pp. 16).—Directions for field studies of birds, flowers, gardening, insects, pond life, shrubs, spiders, soils, trees, vines, and weeds are given, together with topics for fall collections.

Suggestions for winter nature-study, Helen M. Reynolds and G. H. Trafton (Mankato, Minn.: State Normal School [1914], pp. 8).—This contains suggestive outlines for holiday, home, health, and weather studies, types of lessons on insect homes, an outline of a plan for teaching, with the dog as subject, and references to nature literature and songs.

Indian school gardens in eastern Oklahoma, J. B. Brown (*Red Man, 6* (1914), No. 10, pp. 434-437).—The author gives an account of Indian school gardening work in Oklahoma and suggests important elements entering into successful school gardening.

School gardening in Portland, Oregon, ALICE V. JOYCE (Nature-Study Rev., 10 (1914), No. 7, pp. 275-281, figs. 2).—The author gives an account of the establishment and activities of school gardens in Portland, Oreg., and calls attention to some valuable results from the gardens.

MISCELLANEOUS.

Twenty-second Annual Report of Minnesota Station, 1914 (Minnesota Sta. Rpt. 1914, pp. 72).—This contains the organization list, a financial statement for the federal funds for the fiscal year ended June 30, 1914, and for the state funds for the fiscal year ended July 31, 1914, and a report of the director summarizing the work of the station and its substations. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Twenty-seventh Annual Report of New York Cornell Station, 1914 (New York Cornell Sta. Rpt. 1914, pp. CLXXXII+1161, pls. 43, figs. 315, map 1).— This contains the organization list, reports of the director of the station and heads of departments, a financial statement as to the federal funds for the fiscal year ended June 30, 1914, and as to the state funds for the fiscal year ended September 30, 1914, and reprints of Bulletins 336–350, Memoirs 3 and 4, and Circulars 21–26, previously noted, and Bulletins 351 and 352 abstracted elsewhere in this issue.

Report of Oregon Station, 1913–14, J. WITHYCOMBE (Oregon Sta. Rpt. 1913–14, pp. 30).—This contains the organization list and a report of the director on the work of the station during the biennium, including synopses of departmental reports, and notes on the substations. The experimental work recorded is for the most part abstracted elsewhere in this issue

Report of the Eastern Oregon Branch Experiment Station, 1913–14, R. WITHYCOMBE (Oregon Sta., Rpt, East. Oreg. Sta., 1913–14, pp. 15, figs. 11).—An account of the history, development, and present facilities of the substation at Union, Oreg., with a discussion of its object and importance.

Annual report of the director of the experiment station on work done under the local experiment law in 1914, J. F. Duggar (Alabama Col. Sta. Circ. 31 (1915), pp. 31).—This includes a report by the director on the progress of the work under this law (E. S. R., 24, p. 400), a financial statement for the year, and reports from heads of departments, including detailed reports of boys' and girls' club work.

List of bulletins (West Virginia Sta. Circ. 10 (1914), pp. 4).—A list of the station bulletins, inspection bulletins, and circulars, and of the extension bulletins, available for distribution.

NOTES

Georgia Station.—A horse and mule barn of concrete construction, 80 by 59 feet, has been completed.

Iowa College.—A special convocation was held May 14 in honor of those members of the faculty who had been in service for at least a quarter of a century. The guests of honor were Vice-president E. W. Stanton, in service since 1874, Gen. J. R. Lincoln, commandant, Herman Knapp, secretary, both in service since 1883, A. A. Bennett, professor emeritus of chemistry, in service since 1885, and Dr. L. H. Pammel, professor of botany and botanist, in service since 1889.

Kansas College.—A new state law effective July 1 provides for the formation of county farm bureaus for the employment of a county agent and other demonstration work. A bureau must enroll 25 per cent of the bona fide farmers of the county under a constitution approved by the college and must raise at least \$800 for equipment. Bureaus complying with these provisions may receive from \$800 to \$1,600 per annum from state and federal funds toward the salary of a county agent and a like sum from the county funds for salary and expenses.

Adjoining counties in the western part of the State may organize joint bureaus under substantially the same conditions, and bureaus already organized which comply with the requirements and provide the necessary equipment may be utilized. The county agents are to be selected by the executive board of the bureau and must have had at least 5 years' experience in practical farm work. All expenditures are to be made subject to the approval of the extension department of the college.

A three-day meeting for the Pottawatomie Indians at their reservation in Jackson County was held by the extension staff April 26–28.

Nevada University and Station.—Some interesting results have recently been obtained in the studies of certain biological questions connected with the life history of *Heterodera radicicola*, the potato eelworm. It is hoped that from these a new method may be suggested for controlling this pest.

The extension division is to revive the publication of *Better Farming*, formerly issued by the station as a means of bringing it into contact with the farmer. Many requests for the continuance of the publication have been received and the station will have access to its columns much as in the past.

Oregon College.—G. V. Copson, now specializing in dairy bacteriology in the University of Berne, has been appointed instructor in pathological and dairy bacteriology.

Wisconsin University.—Ray II. Roberts has been appointed instructor in extension work in horticulture,

Wyoming University and Station.—Henry G. Knight, dean of the college of agriculture and director of the station, Dr. O. L. Prien, veterinarian, and J. E. McWilliams, acting animal husbandman, have been granted a year's leave of absence beginning September 1, to be spent in study at the University of Illinois, Northwestern University, and the Michigan Agricultural College, respectively. President C. A. Duniway will act as director of the station during this period.

900
